- The solution should be clear and colourless to slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over at least 60 seconds.

#### **Continuous intravenous infusion**

Preparation and administration

Check that you have selected the correct strength of vial.

- 1. Withdraw 500 mg of ketamine.
- 2. Remove an equivalent volume of infusion fluid from a 500-mL bag of NaCl 0.9% or Gluc 5%.
- Add the ketamine to the prepared infusion bag to give a solution containing 1 mg/mL. Mix well. (Alternatively, following the same procedure, add 500 mg to 250 mL infusion fluid to give a solution containing 2 mg/mL.)
- 4. The solution should be clear and colourless to slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by continuous IV infusion via a volumetric infusion device. The rate of infusion is dependent on the patient's reaction and response to anaesthesia.

Fluid restriction: solutions containing up to 50 mg/mL have been used (unlicensed).

# Ketoprofen

#### 50 mg/mL solution in 2-mL ampoules

- · Ketoprofen is a non-steroidal anti-inflammatory drug (NSAID).
- It may be given by the IM route for the management of pain and inflammation in acute exacerbations of rheumatic disease and other musculoskeletal disorders.

#### **Pre-treatment checks**

- Do not administer to patients with active peptic ulceration or a history of recurrent peptic ulceration or chronic dyspepsia, severe renal failure, sensitivity to aspirin or other NSAIDs, severe heart failure.
- · Use with caution in renal impairment.

#### Biochemical and other tests

Blood pressure Renal function: U, Cr, CrCl (or eGFR)

#### Dose

**All indications**: 50–100 mg every 4 hours up to a maximum of 200 mg in 24 hours. The injection should not normally be used for more than 3 days.

Dose in renal impairment: dose as in normal renal function but avoid if possible.

#### Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by deep IM injection into the gluteal muscle.

| This assessment is based on the full range of propagation and administration options described in the |                                                                                  |  |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Oruvail IM injection (accessed 15 October 2008).

# **Ketorolac trometamol**

#### 10 mg/mL and 30 mg/mL solution in 1-mL ampoules

- Ketorolac trometamol is a non-steroidal anti-inflammatory drug (NSAID).
- · It is used for the short-term management of moderate to severe acute postoperative pain.

#### **Pre-treatment checks**

- Avoid in active or previous peptic ulcer, cerebrovascular bleeding, haemorrhagic diatheses, the complete or partial syndrome of nasal polyps, angioedema or bronchospasm, hypovolaemia or dehydration, moderate or severe renal impairment (Cr >160 micromol/L) and severe heart failure.
- Do not use in patients who have had operations with a high risk of haemorrhage or incomplete haemostasis or during pregnancy, labour, delivery or lactation.
- Do not give to women attempting to conceive as the use of ketorolac may impair female fertility.
- Do not give with aspirin or other NSAIDs (including COX 2 inhibitors), pentoxifylline, probenecid, lithium or patients on anticoagulants (including low-dose heparin).
- Caution in uncontrolled *†BP*, heart failure, ischaemic heart disease and cerebrovascular disease.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Blood pressure | FBC                                   |
|----------------|---------------------------------------|
| Bodyweight     | Renal function: U, Cr, CrCl (or eGFR) |

#### Dose

Postoperative pain: 10 mg by IM or IV injection followed by 10–30 mg every 4–6 hours as required.

- In the initial postoperative period ketorolac may be given every 2 hours if needed.
- Maximum daily dose: 90 mg (60 mg for elderly patients and patients <50 kg bodyweight; 40 mg for oral therapy).
- Convert to oral medication as soon as practicable; the oral dose should not exceed 40 mg on the day
  the formulation is changed and the combined daily dose should not exceed the maximum daily dose.
- Because of the high incidence of reported adverse effects, in the UK the maximum licensed duration of therapy is: parenteral therapy 2 days; oral therapy 7 days.

Dose in renal impairment: adjusted according to creatinine clearance.

- CrCl >20-50 mL/minute: maximum 60 mg daily.
- CrCl <10-20 mL/minute: avoid if possible.

#### **Intramuscular Injection**

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. The solution should be clear and colourless or slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over at least 15 seconds.

# Labetalol hydrochloride

#### 5 mg/mL solution in 20-mL ampoules

- Labetalol hydrochloride is a mixed alpha- and beta-adrenoceptor blocker that lowers BP by decreasing peripheral vascular resistance.
- It is used IV for rapid control of severe *†BP*, including severe *†BP* of pregnancy.
- Patients should always receive the drug while in the supine or left lateral position. Raising the
  patient into the upright position within 3 hours of dosing should be avoided since excessive
  postural LBP may occur.

#### **Pre-treatment checks**

- Treatment should be avoided in sick sinus syndrome, ↓BP, heart block greater than first degree, ↓pulse (<45–50 bpm), cardiogenic shock and overt heart failure.
- Use with caution in patients with a history of wheezing or asthma and peripheral circulatory conditions.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure LFTs Pulse

#### Dose

**For rapid reduction of BP:** 50 mg by IV injection repeated at 5-minute intervals as necessary until a satisfactory response occurs. The total dose should not exceed 200 mg.

**Hypotensive anaesthesia:** the recommended starting dose is 10-20 mg by IV injection depending on the age and condition of the patient. Patients for whom halothane is contraindicated usually require a higher initial dose of 25-30 mg. If satisfactory  $\downarrow$ BP is not achieved after 5 minutes, additional doses of 5-10 mg should be given at 5-minute intervals until the desired response is achieved.

**Hypertension of pregnancy:** initially 20 mg/hour by IV infusion. The dose may be doubled every 30 minutes until a satisfactory response or a dosage of 160 mg/hour is reached. Occasionally, higher doses may be necessary.

**Hypertensive episodes following acute MI:** 15 mg/hour by IV infusion, gradually increased to a maximum of 120 mg/hour as necessary.

**Hypertension due to other causes:** 2 mg/minute by IV infusion until a satisfactory response is obtained; the infusion should then be stopped. The effective cumulative dose is usually in the range of 50-200 mg depending on the severity of the  $\uparrow$ BP. Larger doses may be required particularly in patients with phaeochromocytoma.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration. Discard if present.
- 3. Give by IV injection over at least 1 minute.

#### **Continuous intravenous infusion**

#### Preparation of a 1 mg/mL solution (other strengths may be used)

1. Withdraw and discard 10 mL from a 250-mL infusion bag containing compatible infusion fluid (usually Gluc 5%).

- 2. Withdraw 300 mg (60 mL) of labetalol injection solution from three ampoules using a syringe and add to the remaining 240 mL of infusion fluid and mix well. This gives a solution containing 1 mg/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

Give by IV infusion via a volumetric infusion device at a rate appropriate to dosing regimen.

**Fluid restriction:** there are anecdotal reports of undiluted injection solution being given (unlicensed) via syringe pump in critical care situations.

# Lacosamide

#### 10 mg/mL solution in 20-mL vials

- · Lacosamide is an antiepileptic agent.
- It is used as adjunctive therapy in partial seizures with or without secondary generalisation in patients aged 16 years and older.
- It is used parenterally in patients normally maintained on lacosamide when the oral route is temporarily unavailable.

#### **Pre-treatment checks**

- Avoid in known second- or third-degree atrioventricular (AV) block.
- Caution in patients with known conduction problems or severe cardiac disease such as a history of
  myocardial infarction or heart failure (prolongations in PR interval have been observed).

#### Biochemical and other tests (not all are necessary in an emergency situation)

LFTs Renal function: U, Cr, CrCl (or eGFR)

#### Dose

For existing patients with epilepsy switched from oral maintenance to parenteral dosing, no adjustment of dose or frequency of lacosamide is necessary.

There is no experience of parenteral treatment extending beyond 5 days.

**Patients previously established on oral therapy:** doses are given by IV infusion at the same dose and frequency as previous oral therapy.

**Initiation of treatment in patients temporarily unable to tolerate oral therapy:** 50 mg twice daily by IV infusion increased every 7 days by 50 mg twice daily to a maximum of 200 mg twice daily.

Dose in renal impairment: adjusted according to creatinine clearance,

- CrCl ≤30 mL/minute: maximum daily dose 250 mg.
- Haemodialysis: a supplement of up to 50% of the divided daily dose should be given directly after the end of the session.

**Dose in hepatic impairment:** no adjustment for mild to moderate hepatic impairment. Not studied in severe hepatic impairment.

#### Intravenous infusion

#### Preparation and administration

- 1. Withdraw the required dose. Infuse undiluted or mix with a convenient volume of compatible infusion fluid, e.g. 100 mL NaCl 0.9%.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 15-60 minutes.

### 492 | Lacosamide

| Common and serious<br>undesirable effects | Common: Depression, dizziness, headache, balance disorder, coordination<br>abnormal, memory impairment, cognitive disorder, somnolence, tremor,<br>nystagmus, diplopia, vision blurred, nausea, vomiting, constipation, flatulence,<br>pruritus, gait disturbance, asthenia, fatigue, falls.                                  |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pharmacokinetics                          | Elimination half-life is about 13 hours; the major metabolite has an elimination half-life of 15-23 hours.                                                                                                                                                                                                                    |
| Significant<br>interactions               | <ul> <li>The following may \$\laccosamide levels or effect:<br/>antidepressants-SRIs (\$\phickle convulsive threshold), antidepressants-tricyclic<br/>(\$\phickle convulsive threshold), antidepressants-tricyclic, related (\$\phickle convulsive<br/>threshold), mefloquine, St John's wort (avoid combination).</li> </ul> |
| Action in case of overdose                | There is no specific antidote. Use general supportive measures, which may include haemodialysis if necessary.                                                                                                                                                                                                                 |
| Counselling                               | Treatment with lacosamide has been associated with dizziness that could <i>\risk</i> of accidental injury or falls. Counsel patient to exercise caution until they are familiar with the potential effects.                                                                                                                   |

### **Bibliography**

SPC Vimpat 50 mg, 100 mg, 150 mg and 200 mg film-coated tablets, 15 mg/mL syrup and 10 mg/mL solution for infusion (accessed 10 October 2009).

# Lanreotide

# 60 mg, 90 mg, 120 mg viscous solution in pre-filled syringes, 30-mg dry powder vials with solvent

- · Lanreotide acetate is a somatostatin analogue with similar properties to octreotide.
- It is used in the symptomatic management of neuroendocrine tumours, particularly carcinoid syndrome, and also in the treatment of acromegaly and thyrotrophic adenomas.
- · Doses are usually expressed in terms of lanreotide base.

#### **Pre-treatment checks**

· Do not give if the patient is hypersensitive to lanreotide or related peptides.

 Use with caution in diabetes mellitus and if there is a history of gall stones (consider gall bladder echography).

#### **Biochemical tests**

LFTs Renal function: U, Cr, CrCl (or eGFR) TFTs (possibly)

#### Dose

#### Acromegaly:

- Somatuline Autogel: initially 60 mg every 28 days by SC injection (if a somatostatin analogue not previously given), adjusted according to response. For patients previously treated with a somatostatin analogue, consult product literature for initial dose.
- Somatuline LA: initially 30 mg by IM injection every 14 days, increased to 30 mg every 7–10 days according to response.

#### 494 | Lanreotide

#### Neuroendocrine tumour:

- Somatuline Autogel: initially 60–120 mg every 28 days by SC injection with subsequent adjustment according to the degree of symptomatic relief.
- Somatuline LA: initially 30 mg by IM injection every 14 days, increased to 30 mg every 7–10 days according to response.

#### **Thyroid tumours:**

 Somatuline LA: initially 30 mg by IM injection every 14 days, increased to 30 mg every 10 days according to response.

#### Intramuscular injection (Somatuline LA depot injection only)

Preparation and administration (see package insert for full details)

- 1. Attach one of the needles to syringe supplied and reconstitute the vial with the solvent provided (**do not remove the syringe** at this stage).
- Shake the vial gently from side to side 20–30 times to obtain a homogenous suspension with a milky appearance.
- 3. **Do not invert the vial**. Withdraw the entire contents of the vial (there is an overage in the vial to account for the small amount remaining in the vial).
- 4. Without delay, give by IM injection into the buttock.

#### Subcutaneous injection (Somatuline Autogel pre-filled syringe only)

#### Preparation and administration (see package insert for full details)

- 1. Remove the correct strength of pre-filled syringe from the fridge 30 minutes prior to use.
- 2. Upon opening the package, use immediately.
- 3. Give by deep SC injection (at 90° to the skin and inserting the needle to its full length) into the upper outer quadrant of the buttock. The upper outer thigh may be used if the patient is self-administering. Use alternate sides for subsequent injections.

# Lenograstim (recombinant human granulocyte colony-stimulating factor, rHuG-CSF)

# 13.4 million units (105 micrograms) and 33.6 million units (263 micrograms) dry powder vials with solvent (WFI)

- Lenograstim is a recombinant glycosylated human granulocyte-colony stimulating factor (rHuG-CSF) that acts primarily on neutrophil precursors to increase neutrophil levels.
- It is used to treat or prevent neutropenia in patients receiving myelosuppressive cancer chemotherapy, to reduce the duration of neutropenia in patients undergoing bone marrow transplantation and to mobilise peripheral blood progenitor cells in blood stem cell transplantation.

#### **Pre-treatment checks**

- Contraindicated in myeloid malignancy (other than *de novo* AML); in patients with *de novo* AML aged <55 years; and/or in patients with *de novo* AML with good cytogenetics.
- Not be used in patients with secondary AML, myelodysplasia or chronic myelogenous leukaemia.
- Use with extreme caution in any pre-malignant myeloid condition such as myelodysplastic syndrome.
- Check recent pulmonary history (recent history of pulmonary infiltrates or pneumonia \u03c6risk of pulmonary adverse events).
- Confirm whether women of child-bearing potential are pregnant or breast feeding (contraindicated unless benefit outweighs risk, at discretion of clinician).
- Prior treatment with certain cytotoxic agents and/or radiotherapy may compromise effectiveness
  of lenograstim in generating mobilisation of sufficient PBPCs, and alternative forms of treatment
  may be needed.
- Potential PBPC donors should be <60 years of age and cannot undergo apheresis if anticoagulated, or if they have known problems with haemostasis; therefore confirm relevant history prior to lenograstim treatment.
- If the patient is receiving cytotoxic chemotherapy, the first dose of lenograstim must not given in the first 24 hours following the completion of the cycle of chemotherapy.

#### Biochemical and other tests

Body surface area for certain indications (and therefore height and bodyweight) FBC

#### Dose

**Cytotoxic-induced neutropenia:** 19.2 million units (150 micrograms) per  $m^2$  by SC injection once daily.

Give the first dose a minimum of 24 hours after cytotoxic therapy and continue until the neutrophil count is within the acceptable range.

**Following bone marrow transplantation:** 19.2 million units (150 micrograms) per  $m^2$  by IV infusion once daily. Give the first dose the day after transplantation and continue until the neutrophil count is within the acceptable range. For timing of leucopheresis, consult product literature.

**Mobilisation of PBPCs (used alone):** 1.28 million units (10 micrograms) per kg by SC injection once daily for 4–6 consecutive days.

**Mobilisation of PBPCs after myeloablative therapy:** 19.2 million units (150 micrograms) per  $m^2$  by SC injection once daily. Give the first dose a minimum of 24 hours after cytotoxic therapy and continue until the neutrophil count is within the acceptable range. For timing of leucopheresis, consult product literature.

#### **Subcutaneous injection**

#### Preparation and administration

- 1. Withdraw the entire contents of the solvent ampoule and add to the vial using the 19G needle provided.
- Agitate the vial gently until the powder has completely dissolved but do not shake vigorously. The solution then contains either 13.4 million units (105 micrograms)/mL or 33.6 million units (263 micrograms)/mL, depending on the vial size used.
- 3. Withdraw the required dose using the 19G needle then change to the 26G needle provided.
- 4. Give by SC injection. Rotate injection sites for subsequent injections to avoid bruising/bleeding.

#### Intermittent intravenous infusion

#### Preparation and administration

- 1. Withdraw the entire contents of the solvent ampoule and add to the vial using the 19G needle provided.
- Agitate the vial gently until the powder has completely dissolved but do not shake vigorously. The solution then contains either 13.4 million units (105 micrograms)/mL or 33.6 million units (263 micrograms)/mL, depending on the vial size used.
- 3. Withdraw the required dose using the 19G needle and add to a suitable volume of NaCl 0.9% or Gluc 5% (use a maximum of 50 mL for 13.4 million unit vial; use a maximum of 100 mL for 33.6 million unit vial).
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by IV infusion over 30 minutes.

# Lepirudin

#### 50-mg dry powder vial

- Lepirudin is a recombinant hirudin that is a direct inhibitor of thrombin.
- It is used as an anticoagulant in the management of thromboembolic disorders in patients with HIT type II requiring parenteral therapy.

#### **Pre-treatment checks**

- Diagnosis should be confirmed by the HIPAA (heparin induced platelet activation assay) or an equivalent test.
- It is inadvisable to use if there is active bleeding.
- Caution should be taken in the following conditions with a careful balance of risk versus benefit: recent puncture of large vessels or organ biopsy; anomaly of vessels or organs; recent

#### 500 | Lepirudin

cerebrovascular accident, stroke, or intracerebral surgery; severe uncontrolled  $\uparrow$ BP; bacterial endocarditis; advanced renal impairment; haemorrhagic diathesis; recent major surgery; recent bleeding (e.g. intracranial, GI, intraocular, pulmonary); overt signs of bleeding; recent active peptic ulcer; age >65 years.

- · Anaphylaxis is more likely if the patient has had previous exposure to lepirudin.
- Ensure that resuscitation facilities are available.

Biochemical and other tests (not all are necessary in an emergency situation)

| APTT ratio     | LFTs (serious impairment may result in enhance-   |
|----------------|---------------------------------------------------|
| Blood pressure | ment of the anticoagulant effect of lepirudin due |
| Body weight    | to impaired production of vitamin K-dependent     |
| FBC            | coagulation factors)                              |
|                | Renal function: U, Cr, CrCl (or eGFR)             |

#### Dose

**Standard dose**: 0.4 mg/kg by slow IV injection (see Table L1). This is followed by 0.15 mg/kg/hour (maximum 16.5 mg/hour) by IV infusion for 2–10 days or longer (see Table L1). Check APTT ratio 4 hours after the start of therapy and adjust the infusion rate according to APTT ratio (see Monitoring below).

Dose in renal impairment: the dose is adjusted according to creatinine clearance (see Table L1):

- CrCl 45-60 mL/minute: reduce loading dose to 0.2 mg/kg and infusion rate to 50% of original.
- CrCl 30-44 mL/minute: reduce loading dose to 0.2 mg/kg and infusion rate to 30% of original.
- CrCl 15-29 mL/minute: reduce loading dose to 0.2 mg/kg and infusion rate to 15% of original.
- CrCl <15 mL/minute: avoid using or stop infusion if already started.

In haemodialysis patients or cases of acute renal failure, IV bolus doses of 0.1 mg/kg may be used on alternate days, according to response.<sup>1</sup>

Dose in hepatic impairment: there is no experience in patients with significant liver impairment.

#### **Conversion to oral anticoagulant therapy**

- Initiate oral anticoagulants only after substantial recovery from acute HIT has occurred and platelet counts are normalising.
- When converting to oral anticoagulant therapy, the dose of lepirudin should be reduced gradually until the APTT ratio is just above 1.5, after which therapy with, for example, warfarin can be started.
- Start with modest doses of warfarin (e.g. 2.5-5 mg daily) and do not use a loading dose.
- Overlap lepirudin and warfarin therapy for a minimum of 4–5 days until the desired INR has been achieved.

#### Intravenous injection

#### Preparation and administration

- 1. Reconstitute one 50-mg vial with 1 mL WFI or NaCl 0.9 % and shake gently for up to 3 minutes to obtain a clear, colourless solution containing 50 mg/mL.
- Withdraw 1 mL into a 10-mL syringe and dilute to 10 mL with NaCl 0.9% or Gluc 5% to give a solution containing 5 mg/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Expel any excess lepirudin to give the required dose (see Table L1).
- 5. Give by IV injection over 3–5 minutes then follow with the continuous infusion.

 Table L1
 Lepirudin dose adjusted according to bodyweight and renal function

<sup>a</sup>lf CrCl <15 mL/minute, avoid using lepirudin or stop infusion if already started.

### Continuous intravenous infusion via syringe pump

#### Preparation and administration

- 1. Reconstitute each of two 50-mg vials with 1 mL WFI or NaCl 0.9 % and shake gently for up to 3 minutes to obtain a clear, colourless solution containing 50 mg/mL.
- 2. Make 100 mg (2 mL) up to 50 mL in a syringe pump with NaCl 0.9% or Gluc 5%.
- 3. Cap the syringe and mix well to give a solution containing 2 mg/mL.
- 4. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by continuous IV infusion at the correct rate for the patient's weight and renal function (see Table L1).
- 6. Prepare a fresh syringe every 12 hours.

| Counselling                                            | Patients should be informed that they have received lepirudin (owing to risk associated with future re-exposure).                    |                                                                                                                                                                                                                                                                                                             |  |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Refludan 50 mg powder for solution for injection or infusion (accessed 19 August 2009).

# Leuprorelin acetate (leuprolide acetate)

# 3.75-mg dry powder vial with 1 mL solvent in prefilled syringe (Prostap SR) 11.25-mg dry powder vial with 2 mL solvent in prefilled syringe (Prostap 3)

- · Leuprorelin acetate is a synthetic analogue of gonadorelin (gonadotrophin-releasing hormone).
- It is used for the suppression of testosterone in the treatment of prostate cancer.
- It is used in the treatment of endometriosis and uterine fibroids and may also be given before surgery for endometrial ablation.
- · Doses are expressed as leuprorelin acetate.

#### **Pre-treatment checks**

Caution in diabetes and osteoporosis (or those at risk, i.e. chronic alcohol and/or tobacco use, strong family history of osteoporosis, or chronic use of drugs that can reduce bone mass, e.g. anticonvulsants or corticosteroids).

#### Biochemical and other tests

Blood pressure Female patients: confirm that the patient is not pregnant LFTs

#### Dose

**Prostate cancer**: 3.75 mg by SC or IM injection every 28 days or 11.25 mg by SC injection every 12 weeks. An antiandrogen agent may be given for 3 days before until 2–3 weeks after commencement to ↓risk of disease flare, e.g. cyproterone acetate 100 mg three times daily.

**Endometriosis:** 3.75 mg by SC or IM injection every 28 days or 11.25 mg by SC injection every 12 weeks for a maximum of 6 months. Treatment should be initiated during the first 5 days of the menstrual cycle. Supplementary combined HRT may  $\downarrow$ bone mineral density loss and vasomotor symptoms.

**Endometrial preparation prior to intrauterine surgery**: 3.75 mg by SC or IM injection 5–6 weeks prior to surgery. Therapy should be initiated during days 3–5 of the menstrual cycle.

**Preoperative management of uterine fibroids**: 3.75 mg by SC or IM injection every 28 days usually for 3–4 months but for a maximum of 6 months. If anaemia is present due to uterine fibroids, ensure that iron supplementation is prescribed.

#### Subcutaneous injection

#### Preparation and administration

- 1. Remove the cap from the vial of powder and from the pre-filled syringe containing the solvent.
- 2. Attach a 23G needle securely to the syringe and inject the whole contents of the syringe into vial of powder. Remove the syringe/needle and keep aseptic.
- 3. Shake the vial gently for 15-20 seconds to produce a uniform cloudy suspension.
- 4. Immediately withdraw the whole vial contents, taking care to exclude air bubbles. The injection should be given as soon as possible after mixing. If any settling of suspension occurs in the vial or syringe, shake gently to re-suspend.
- Attach a new 23G needle and give by SC injection. Aspirate before injection to avoid inadvertent intravascular injection.

### Intramuscular injection (Prostap SR only)

#### Preparation and administration

- 1. Remove the cap from the vial of powder and from the pre-filled syringe containing the solvent.
- 2. Attach a 23G needle securely to the syringe and inject the whole contents of the syringe into vial of powder. Remove the syringe/needle and keep aseptic.
- 3. Shake the vial gently for 15–20 seconds to produce a uniform cloudy suspension.
- 4. Immediately withdraw the whole vial contents, taking care to exclude air bubbles. The injection should be given as soon as possible after mixing. If any settling of suspension occurs in the vial or syringe, shake gently to re-suspend.
- 5. Attach a 21G needle and give by IM injection. Aspirate before injection to avoid inadvertent intravascular injection.

# Levetiracetam

#### 100 mg/mL solution in 5-mL vials

- · Levetiracetam is an antiepileptic drug.
- It is used as monotherapy of partial seizures with or without secondary generalisation, and as adjunctive therapy in various types of epilepsy.
- It is usually used parenterally in patients normally maintained on levetiracetam when the oral route is temporarily unavailable.

#### **Pre-treatment checks**

Pregnancy test if possible.

Biochemical and other tests (not all are necessary in an emergency situation)

Bodyweight LFTs Renal function: U, Cr, CrCl (or eGFR)

#### Dose

For existing patients with epilepsy switched from oral maintenance to parenteral dosing, no adjustment of dose or frequency of levetiracetam is necessary. There is no experience of parenteral treatment extending beyond 4 days.

**Patients previously established on oral therapy:** doses are given by IV infusion at the same dose and frequency as in previous oral therapy.

#### Initiation of treatment in patients temporarily unable to tolerate oral therapy:

- Monotherapy for partial seizures with or without secondary generalisation: initially 250 mg by IV infusion twice daily (increased according to response every 2 weeks).
- *Adjunctive therapy:* initially 500 mg by IV infusion twice daily (increased according to response every 2 weeks).

Dose in renal impairment: the maximum dose is adjusted according to creatinine clearance:

- CrCl 50-79 mL/minute: maximum dose 1 g twice daily.
- CrCl 30-49 mL/minute: maximum dose 750 mg twice daily.
- CrCl <30 mL/minute: maximum dose 500 mg twice daily.
- CrCl <10 mL/minute in patients undergoing dialysis: maximum dose 1 g once daily.

**Dose in hepatic impairment:** no dose adjustment is needed in patients with mild to moderate hepatic impairment.

#### Intermittent intravenous infusion

Preparation and administration

- 1. Withdraw the required dose and add to a suitable volume of compatible infusion fluid, e.g. a minimum of 100 mL NaCl 0.9%).
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 15 minutes.

#### 508 | Levetiracetam

#### Bibliography

SPC Keppra 250, 500, 750 and 1000 mg film-coated tablets, 100 mg/ml oral solution and 100 mg/ml concentrate for solution for infusion (accessed 21 April 2008).

# Levocarnitine (L-carnitine)

#### 200 mg/mL solution in 5-mL ampoules

- Carnitine is an amino acid derivative that is an essential co-factor of fatty acid metabolism. It
  occurs as distinct L- and D-isomers, although only the L-isomer is believed to be biologically active.
- Levocarnitine is used in the treatment of primary carnitine deficiency and in carnitine deficiency resulting from various defects of intermediary metabolism.
- It has been used to treat carnitine deficiency in haemodialysis patients. The first 3 months of therapy is usually given IV to replenish normal muscle levels, after which maintenance doses may be given orally. All doses are given at the end of haemodialysis sessions.
- · Levocarnitine has also been used in cases of valproate toxicity (unlicensed indication).

#### **Pre-treatment checks**

- · Caution should be exercised in diabetic patients receiving insulin or oral treatment.
- Patients with severe renal impairment should not be given high oral doses for prolonged periods owing to accumulation of toxic metabolites (not shown to occur to the same extent after IV doses).

#### **Biochemical tests**

Free and acyl carnitine levels in plasma and urine.

#### 510 | Levocarnitine

#### Dose

Primary deficiency: up to 25 mg/kg four times daily.

Secondary deficiency: 20 mg/kg after each dialysis session (dosage adjusted according to carnitine concentration). Treatment should be continued for at least 3 months.

For valproate toxicity in patients who have hyperammonaemia or hepatotoxicity (unlicensed):

It is essential to consult a poisons information service, e.g. Toxbase at www.toxbase.org (password or registration required) for full details of the management of valproate toxicity.

Consider IV administration of levocarnitine in patients who have taken a massive valproate overdose and who have hyperammonaemia or hepatotoxicity.<sup>1</sup> Discuss with your local poisons information service.

#### **Intravenous injection**

Preparation and administration

- 1. Withdraw the required dose.
- 2. The solution should be clear and colourless to light straw coloured. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 2-3 minutes.

#### Intermittent intravenous infusion (unlicensed use for valproate toxicity)

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. May be infused undiluted, or added to a suitable volume of compatible infusion fluid.
- 3. The solution should be clear and colourless to light straw coloured. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 30 minutes (loading dose) or 10-30 minutes (subsequent doses).

# Levofloxacin

#### 5 mg/mL solution in 100-mL infusion bottles

- · Levofloxacin hemihydrate is an isomer of the fluorinated quinolone antibacterial ofloxacin.
- It is used to treat infections cause by susceptible Gram-positive and Gram-negative bacteria.
- Levofloxacin is rapidly and well absorbed from the GI tract following oral dosing so the IV route should be used only when the oral route is unavailable.
- Doses are expressed in terms of the base: Levofloxacin 250 mg = 256 mg levofloxacin hemihydrate.

#### **Pre-treatment checks**

- · Do not give if there is known hypersensitivity to quinolone antibacterials.
- Avoid in patients with a past history of tendinitis or a history of epilepsy, or in pregnant or breastfeeding women.
- Use with caution if there is a history of psychiatric disease or in patients with latent or actual defects in G6PD activity.
- · Patients should be well hydrated and asked to drink fluids liberally.

#### Biochemical and other tests

Blood pressure LFTs Renal function: U, Cr, CrCl (or eGFR)

#### Dose

Community-acquired pneumonia: 500 mg once or twice daily.

**Complicated urinary tract infections (including pyelonephritis)**: 250 mg daily, increased in severe infections.

Skin and soft-tissue infections: 500 mg twice daily.

**Dose in renal impairment**: adjusted according to creatinine clearance:

- CrCl >20-50 mL/minute: initial dose 250-500 mg then reduce dose by 50%.
- CrCl 10-20 mL/minute: initial dose 250-500 mg then 125 mg every 12-24 hours.
- CrCl <10 mL/minute: initial dose 250-500 mg then 125 mg every 24-48 hours.

#### Intermittent intravenous infusion

#### Preparation and administration

- 1. The infusion is pre-prepared for use. It should be clear and greenish yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 2. Give by IV infusion over at least 30 minutes for 250 mg (at least 60 minutes for 500 mg).

# Levomepromazine (methotrimeprazine)

#### 25 mg/mL solution in 1-mL ampoules

- Levomepromazine hydrochloride is a phenothiazine derivative.
- It is used as an antiemetic, antihistamine and sedative in palliative care.
- It may also be given by continuous SC infusion in palliative care for the management of pain, nausea and vomiting, and the accompanying restlessness or distress.
- Doses below are expressed in terms of levomepromazine hydrochloride.

#### **Pre-treatment checks**

- · Avoid or use with caution in patients with liver dysfunction or cardiac disease.
- Patients receiving large initial doses should be kept in bed as it may have a hypotensive effect.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Blood pressure | Electrolytes: serum Ca, Mg, K |
|----------------|-------------------------------|
| ECG            | LFTs                          |

#### Dose

**Standard dose**: 12.5–25 mg by IM or IV injection every 6 to 8 hours. In cases of severe agitation the dose may be increased to 50 mg.

#### Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose and dilute with an equal volume of NaCl 0.9%.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 3-5 minutes.

### Bibliography

SPC Nozinan (accessed 26 August 2008).

# Lidocaine (lignocaine) hydrochloride – intravenous administration

# 10 mg/mL (1%) in 10-mL pre-filled syringes; 20 mg/mL (2%) in 5-mL pre-filled syringes 10 mg/mL (1%) solution and 20 mg/mL (2%) solution in 2-mL, 5-mL, 10-mL and 20-mL ampoules

1 mg/mL (0.1%) and 2 mg/mL (0.2%) in Gluc 5% in 500-mL infusion bags

- · Lidocaine is a local anaesthetic and it also has class 1b antiarrhythmic effects.
- It is used IV to treat ventricular arrhythmias, especially after MI.
- Doses are expressed in terms of lidocaine hydrochloride.

Products containing adrenaline (epinephrine) or preservatives **must not** be given by IV injection.

#### **Pre-treatment checks**

- · Caution in patients with porphyria.
- In IV therapy resuscitative equipment and drugs should be immediately available for the management of severe adverse cardiovascular, respiratory or central nervous system effects.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Possibly prior to IV treatment:

Renal function: U, Cr, CrCl (or eGFR)

ECG Electrolytes: serum K (correct  $\downarrow$ K before commencing therapy)

#### Dose

Ventricular arrhythmias: 100 mg by IV injection in patients without gross circulatory impairment (50 mg in lighter patients or those whose circulation is severely impaired); followed

immediately by 4 mg/minute by IV infusion for 30 minutes, then 2 mg/minute for 2 hours, then 1 mg/minute. Reduce the rate further if infusion is continued beyond 24 hours (rarely required).

- The IV injection dose can be repeated once or twice at intervals of not less than 10 minutes if an infusion is not immediately available.
- Stop the infusion as soon as the basic cardiac rhythm appears to be stable or at the earliest signs of toxicity.

#### Intravenous injection

#### Preparation and administration

- 1. Select the appropriate pre-filled syringe. Expel any excess lidocaine if necessary. Alternatively, withdraw the required dose.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV injection at a rate of 25–50 mg/minute, i.e. give 1% injection at 2.5–5 mL/minute; give 2% injection at 1.25–2.5 mL/minute.

### **Continuous intravenous infusion**

#### Preparation and administration

- Select the correct pre-prepared infusion bag. Alternatively, withdraw the required dose of 1% or 2% injection and add to a suitable volume (usually 500 mL) of Gluc 5% to give a solution containing between 1 mg/mL and 4 mg/mL. Mix well.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion via a volumetric infusion device at the appropriate rate (see Dose above).

# Bibliography

SPC Lidocaine Hydrochloride Injection BP Minijet 1% and 2% (accessed 3 May 2010). SPC Lidocaine Injection BP 1% and 2% w/v, Hameln (accessed 3 May 2010).

# Lidocaine (lignocaine) hydrochloride – local anaesthetic use

10 mg/mL (1%) and 20 mg/mL (2%) solution in 2-mL, 5-mL, 10-mL and 20-mL ampoules 10 mg/mL (1%) with adrenaline (epinephrine) 1 : 200 000 solution in 20-mL and 50-mL vials 20 mg/mL (2%) with adrenaline (epinephrine) 1 : 200 000 solution in 20-mL and 50-mL vials

- · Lidocaine is a local anaesthetic and it also has class 1b antiarrhythmic effects.
- It is used for infiltration anaesthesia and for regional nerve blocks. It has a rapid onset and anaesthesia is usually effective within a few minutes.
- In some preparations a local vasoconstrictor such as adrenaline (epinephrine) is added to ↑speed of
  onset and duration of action and also to ↓toxicity of lidocaine by limiting absorption into the
  general circulation.
- Some multidose vials contain preservatives and these preparations must not be used for spinal, epidural, caudal or IV regional anaesthesia.
- Lidocaine is included in some injections such as depot corticosteroids to prevent pain, itching, and
  other local irritation; it may also be use to reconstitute IM injections of some antibacterials to
  reduce injection site pain.
- A wide range of formulations exists and the listing above is not exhaustive.

#### **Pre-treatment checks**

Caution in patients with porphyria.

Biochemical and other tests (not all are necessary in an emergency situation)

Nil for local anaesthetic use

#### Dose

Products containing adrenaline or preservatives **must not** be given by IV injection. **Important:** When lidocaine is used for local anaesthesia, rapid and extensive absorption may occur resulting in systemic side-effects.

**Infiltration anaesthesia:** dose is determined by patient's weight and the site and nature of the procedure:

- · Maximum dose without adrenaline: 200 mg.
- Maximum dose with adrenaline: 500 mg.

IV regional anaesthesia and nerve blocks: seek expert advice.

(continued)

| Technical information (continued) |                                                                                                                               |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| Excipients                        | Some products contain preservatives. These products must not be used for spinal, epidural, caudal or IV regional anaesthesia. |
| Storage                           | As specified in the individual product literature.                                                                            |

#### Monitoring

There is little need for monitoring when used for local anaesthesia. If it is accidentally given intravenously, see the separate monograph on intravenous administration for monitoring requirements.

### Additional information

| Common and serious<br>undesirable effects | Inadvertent IV dosing during local anaesthetic procedures can cause dizziness, paraesthesia and drowsiness. ↓BP and ↓pulse may lead to cardiac arrest.                                                                                             |  |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Pharmacokinetics                          | Serum lidocaine concentrations are usually insignificant following local use.                                                                                                                                                                      |  |
| Significant interactions                  | None expected when used for local anaesthesia.                                                                                                                                                                                                     |  |
| Action in case of<br>overdose             | Symptoms to watch for: Cardiovascular collapse, seizure, medullary depression.<br>Antidote: No specific antidote; stop administration and give supportive therapy as appropriate, which may include diazepam for seizures and metaraminol for ↓BP. |  |
| Risk rating: GREEN                        | Score = 2<br>Lower-risk product. Risk-reduction strategies should be considered.                                                                                                                                                                   |  |
|                                           |                                                                                                                                                                                                                                                    |  |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Linezolid

#### 2 mg/mL solution in 300-mL infusion bags

- · Linezolid is an oxazolidinone antibacterial.
- It is used for the treatment of Gram-positive infections of the skin and respiratory tract, including those
  due to vancomycin-resistant enterococci and MRSA. It is not effective against Gram-negative organisms.
### 522 | Linezolid

- It is also a reversible, non-selective inhibitor of monoamine oxidase (MAOI), although it does not
  exert an antidepressive effect in antibacterial dose (see Pre-treatment checks and Significant
  interactions below).
- Linezolid has an oral bioavailability of approximately 100%. The parenteral formulation should be used only if the oral route is unavailable.

## **Pre-treatment checks**

- Only give to patients with the following conditions if facilities are available to closely monitor BP: uncontrolled *†BP*, phaeochromocytoma, carcinoid, thyrotoxicosis, bipolar depression, schizoaffective disorder, acute confusional states; or patients taking the following medication: SSRIs, tricyclic antidepressants, 5HT1 agonists (triptans), sympathomimetics, buspirone, pethidine and possibly other opioid analgesics).
- ↑Risk of seizures in patients with a history of seizures.

#### Biochemical and other tests

| Blood pressure            | LFTs                                  |
|---------------------------|---------------------------------------|
| Electrolytes: serum Na, K | Renal function: U, Cr, CrCl (or eGFR) |
| FBC                       |                                       |

## Dose

**Standard dose**: 600 mg twice daily usually for 10–14 days.

Dose in renal impairment: adjusted according to creatinine clearance:1

- CrCl 10-50 mL/minute: dose as in normal renal function
- CrCl <10 mL/minute: dose as in normal renal function. If platelet count drops on a dose of 600 mg twice daily, consider reducing to 600 mg once daily. The two primary metabolites accumulate and have MAOI activity but no antibacterial activity – monitor the patient closely. For patients undergoing dialysis, give the dose after dialysis.

## Intermittent intravenous infusion

- 1. Remove the overwrap only when ready to use. Check for minute leaks by squeezing the bag firmly if the bag leaks, do not use.
- 2. The solution is pre-prepared for use. It should be clear and colourless to yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 30–120 minutes.

| Technical information |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |  |

## 524 | Linezolid

| Additional information                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |  |  |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|--|
| Common and serious<br>undesirable effects | Candidiasis (particularly oral and vaginal candidiasis) or fungal infections,<br>headache, taste perversion (metallic taste), diarrhoea, nausea, vomiting,<br>abnormal LFTs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |  |  |  |
| Pharmacokinetics                          | Elimination half-life is 5 hours. The two primary metabolites accumulate and have MAOI activity but no antibacterial activity.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |  |  |  |
| Significant<br>interactions               | <ul> <li>Linezolid is a reversible non-selective MAOI.</li> <li>Avoid concurrent use of linezolid with the following (see above and BNF for details):<br/>anaesthetics-general, antidepressants-tricyclic, antidepressants-tricyclic related, atomoxetine, bupropion, carbamazepine, duloxetine, entacapone, indoramin, methyldopa, mirtazapine, moclobemide, nefopam, opioid analgesics, rizatriptan, sibutramine, sumatriptan.</li> <li>†Risk of hypertensive crisis if linezolid is given with:<br/>levodopa, MAOIs, methylphenidate, rasagiline, reboxetine, sympathomimetics.</li> <li>†Risk of CNS toxicity if linezolid if given with:<br/>antidepressants-SSRI, antidepressants-tricyclic, clozapine, MAOIs, tetrabenazine, tryptophan, venlafaxine, zolmitriptan.</li> <li>Linezolid may [levels or effect of carbamazepine.</li> </ul> |  |  |  |
| Action in case of<br>overdose             | No cases of overdose have been reported.<br><i>Antidote:</i> No known antidote but haemodialysis is known to remove the two primary<br>metabolites. Stop administration and give supportive therapy as appropriate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |  |  |  |
| Counselling                               | Linezolid is a reversible non-selective MAOI. Advise against consuming large<br>amounts of tyramine-rich foods, e.g. mature cheese, yeast extracts, undistilled<br>alcoholic beverages and fermented soya-bean products such as soy sauce.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |  |  |  |

|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |  |  |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Liothyronine sodium (L-tri-iodothyronine)

#### 20 micrograms dry powder ampoules

- Liothyronine sodium has a similar action to levothyroxine but is more rapidly metabolised and has a faster effect.
- Given IV it is the treatment of choice in severe hypothyroid states and hypothyroid coma when a rapid response is desired.
- Doses may be expressed as liothyronine sodium or liothyronine. Doses below are expressed in terms of liothyronine sodium:

Liothyronine 10 micrograms  $\equiv$  10.3 micrograms liothyronine sodium.

#### **Pre-treatment checks**

- Caution in myxoedema coma as a large dose can precipitate heart failure, especially in elderly
  patients and those with ischaemic heart disease.
- In severe and prolonged hypothyroidism there may be decreased adrenocortical activity. When
  thyroid replacement therapy is started, metabolism is raised at a greater rate than adrenocortical
  activity; this can result in adrenocortical insufficiency so that additional corticosteroid therapy
  may be required.
- An increase in hypoglycaemic therapy may be necessary in patients with diabetes mellitus started on thyroid replacement therapy.

#### Biochemical and other tests

Blood pressure Pulse TFTs

#### Dose

Liothyronine 20 micrograms IV  $\cong$  levothyroxine 100 micrograms or ally.

Oral therapy should be instituted as soon as possible.

When changing from IV to oral therapy, levothyroxine should be introduced gradually, particularly in elderly patients and patients with pre-existing ischaemic heart disease.

Liothyronine must not be given by IM injection (the solution is very alkaline).

**Hypothyroid coma:** 5–20 micrograms by IV injection every 12 hours or more frequently if necessary. No more than 12 hours should elapse between doses to avoid fluctuations in hormone levels. Administration more frequently than every 4 hours does not allow for assessment of therapeutic response between doses.

#### Intravenous injection

- 1. Add 1–2 mL WFI to the ampoule and shake gently until the plug has dissolved.
- 2. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration.
- 4. Give by IV injection over 3-5 minutes.

# Lorazepam

#### 4 mg/mL solution in 1-mL ampoules

- Lorazepam is a short-acting benzodiazepine with anxiolytic, anticonvulsant and central muscle relaxant properties.
- It is used parenterally to provide sedation prior to procedures such as endoscopy, as a premedication before general anaesthesia, to treat status epilepticus and to manage severe acute anxiety or agitation.
- It is also used for rapid tranquillisation in the treatment of acutely disturbed behaviour.

#### **Pre-treatment checks**

- Avoid in acute pulmonary insufficiency, sleep apnoea syndrome, myasthenia gravis and severe hepatic insufficiency.
- · Caution should be used in acute narrow-angle glaucoma.
- Equipment necessary to maintain a patent airway and to support respiration/ventilation should be available in the event of a respiratory arrest.
- Do not give within 1 hour of olanzapine IM injection.

#### Biochemical and other tests (not all are necessary in an emergency)

| Blood pressure | Renal function: U, Cr, CrCl (or eGFR) |
|----------------|---------------------------------------|
| Bodyweight     | Respiratory rate                      |
| LFTs           |                                       |

#### Dose

**Acute anxiety and acute panic attacks**: 25–30 micrograms/kg (usual range 1.5–2.5 mg) repeated every 6 hours if necessary.

#### 528 | Lorazepam

**Premedication:** 50 micrograms/kg (3.5 mg for an average 70 kg man) by IV injection 30–45 minutes before procedure. Sedation will be evident after 5–10 minutes and maximal loss of recall will occur after 30–45 minutes. If the IV and oral routes are not available, give by IM injection 60–90 minutes before the procedure.

Status epilepticus: 4 mg by IV injection. Repeat once after 10 minutes if necessary.

Dose in hepatic impairment: reduce dose and avoid if severe.

## Intravenous injection (preferred route)

Preparation and administration

IV injection should be performed with extreme care to avoid inadvertent intra-arterial injection, which can cause arteriospasm possibly resulting in gangrene.

- 1. Add 1 mL NaCl 0.9% or WFI to the lorazepam ampoule and mix the contents gently to give a solution containing 2 mg/mL.
- 2. Withdraw the required dose.
- 3. Immediately return the remainder of the lorazepam box to the refrigerator (not stable at room temperature for longer than 30 minutes).
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- If treating status epilepticus give by rapid IV injection into a large vein, otherwise give by slow IV injection into a large vein over 3–5 minutes.

## Intramuscular injection

Preparation and administration

IM injection is not recommended; it works no more rapidly than oral administration.

- 1. Add 1 mL NaCl 0.9% or WFI to the lorazepam ampoule and mix the contents gently to give a solution containing 2 mg/mL.
- 2. Withdraw the required dose.
- 3. Immediately return the remainder of the lorazepam box to the refrigerator (not stable at room temperature for longer than 30 minutes).
- 4. Give by deep IM injection into a large muscle.

| Technical information |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |  |  |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

## **Bibliography**

SPC Ativan (accessed 22 January 2008).

# **Magnesium sulfate**

#### 10% solution in 10-mL and 50-mL ampoules: 20% solution in 20-mL ampoules 50% solution in 2-mL, 5-mL and 10-mL ampoules; 4-mL and 10-mL pre-filled syringes 20 mmol in 100 mL NaCl 0.9% (a 'specials' product)

- Magnesium is the second most abundant cation in the intracellular fluid; it is an essential electrolyte and a co-factor in many enzyme systems.
- Normal range for plasma magnesium is 0.75–0.95 mmol/L.
- · Magnesium sulfate injection is used to treat hypomagnesaemia.
- It may also be used in the emergency management of severe asthma and also in eclampsia and preeclampsia (all unlicensed).

| 10% magnesium sulfate injection contains | $0.1g/mL\cong Mg^{2*}~0.4mmol/mL.$  |
|------------------------------------------|-------------------------------------|
| 20% magnesium sulfate injection contains | $0.2g/mL\cong Mg^{2+}$ 0.8 mmol/mL. |
| 50% magnesium sulfate injection contains | $0.5g/mL\cong Mg^{2*}\ 2mmol/mL.$   |

## **Pre-treatment checks**

- Avoid in renal failure, heart block and myocardial damage.
- Avoid in hepatic coma if there is a risk of renal failure.
- · Do not give with high doses of barbiturates, opioids or hypnotics (risk of respiratory depression).
- · Caution if patient is taking cardiac glycosides.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Bodyweight Electrolytes: serum Mg Renal function: U, Cr, CrCl (or eGFR)

#### Dose

Doses should be tailored to individual requirements.

**Mild hypomagnesaemia:** a dose of 4 mmol (1 g) by IM injection every 6 hours for 4 doses has been used, but injections are painful.

**Symptomatic hypomagnesaemia:** 1–2 mmol/kg by IV infusion. Up to a total of 160 mmol may be required over 5 days.

One regimen is to give 0.5 mmol/kg by IV infusion on day 1; then 0.25 mmol/kg by IV infusion on days 2–5, rounding the doses to conveniently measurable volumes.

Asthma (unlicensed): 4.8-8 mmol (1.2-2 g) by IV infusion over 20 minutes.

Ventricular fibrillation in the presence of  $\downarrow$ Mg; arrhythmias including torsade de pointes: 8 mmol (2 g) by slow IV injection.

**Prevention of recurrent seizures in pregnant women with eclampsia (unlicensed):** 16 mmol (4 g) by IV injection or small-volume infusion over 10–15 minutes followed by 4 mmol (1 g)/hour by IV infusion for at least 24 hours after last seizure. If seizures recur then an additional dose of 8–16 mmol (2–4 g) may be given by IV injection or small-volume infusion.

Dose in renal impairment: monitor levels closely and reduce dose as appropriate.

**Fluid restriction:** solutions containing up to 0.4 mmol/mL magnesium sulfate may be given by IV infusion via a peripheral vein; solutions containing up to 0.8 mmol/mL magnesium sulfate may be given by IV infusion via a central line.

## Intravenous infusion (preferred method)

#### Preparation and administration

- 1. Withdraw the required dose and add to a suitable volume NaCl 0.9% or Gluc 5% to give a solution containing a maximum of 0.4 mmol/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Infuse via a volumetric infusion device at a rate appropriate to the indication (usually 4-8 mmol/hour).

## **Intravenous injection**

#### Preparation and administration

- 1. Withdraw the required dose and dilute if necessary with NaCl 0.9% or Gluc 5% to give a solution containing a maximum of 0.8 mmol/mL (i.e. a maximum concentration of 20%).
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by slow IV injection at a rate not exceeding 0.6 mmol/minute (dose is typically given over 5–15 minutes).

## Intramuscular injection (painful, avoid if possible)

- 1. Withdraw the required dose.
- 2. If the injection solution used contains more than 20% magnesium sulfate dilute to 20% before administration, e.g. dilute the 50% injection with at least 1.5 parts WFI.
- 3. Give by deep IM injection.

Moderate-risk product: Risk-reduction strategies are recommended.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# **Mannitol**

#### 100 mg/mL (10%) solution in 250-mL and 500-mL infusion bags 200 mg/mL (20%) solution in 250-mL and 500-mL infusion bags

- Mannitol is a hexahydric alcohol that is an isomer of sorbitol. When infused it increases serum osmolality, which in turn removes fluid from tissues and promotes diuresis.
- It is used as an osmotic diuretic in the treatment of cerebral oedema and in ↑intraocular pressure.

## **Pre-treatment checks**

Do not give in congestive cardiac failure, pulmonary oedema and active intracranial bleeding (except during craniotomy).

Biochemical and other tests (not all are necessary in an emergency situation)

| Bodyweight                | Plasma volume                         |
|---------------------------|---------------------------------------|
| Electrolytes: serum Na, K | Renal function: U, Cr, CrCl (or eGFR) |

#### Dose

**Cerebral oedema and raised intraocular pressure**: 0.25–2 g/kg by IV infusion (preferably via a central line) over 30–60 minutes repeated if necessary 1 or 2 times after 4–8 hours.

### Intravenous infusion

Infusion via a central venous catheter is preferable because of the risk of damage to veins (see Osmolarity below).

- The infusion is pre-prepared for use. It should be clear and colourless. Inspect visually for particulate matter (particularly crystals) or discoloration prior to administration and discard if present.
- 2. Give the required dose by IV infusion over 30-60 minutes using a giving set with an in-line filter.

# **Meptazinol**

#### 100 mg/mL solution in 1-mL ampoules

- Meptazinol hydrochloride is an opioid agonist-antagonist analgesic, with central cholinergic activity. It is reported to have a low incidence of respiratory depression.
- It is used for the acute treatment of moderate to severe pain.
- Doses are expressed in terms of the base:
- Meptazinol  $100 \text{ mg} \cong 116 \text{ mg}$  meptazinol hydrochloride.

#### **Pre-treatment checks**

- Do not use in acute respiratory depression, where there is a risk of paralytic ileus, in †intracranial
  pressure and in head injury, in comatose patients, in acute abdomen, in delayed gastric emptying,
  in chronic constipation, in cor pulmonale or in acute porphyria.
- Caution in JBP, shock, convulsive disorders, supraventricular tachycardias, atrial flutter, chronic
  obstructive pulmonary disease and acute asthma attack, obstructive or inflammatory bowel diseases, biliary tract diseases, alcoholism, prostatic hyperplasia, myasthenia gravis, hypothyroidism
  (reduce dose), adrenocortical insufficiency (reduce dose).
- · Caution in toxic psychosis and pancreatitis.
- Ensure that resuscitation equipment and naloxone are available especially for IV administration.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure and pulse Bodyweight (for obstetric pain) LFTs Pain score Renal function: U, Cr, CrCl (or eGFR) Respiratory rate

#### Dose

Acute pain: 75-100 mg by IM injection, or 50-100 mg by IV injection every 2-4 hours when required.

Obstetric pain: 100-150 mg by IM injection based on bodyweight (approximately 2 mg/kg).

**Dose in renal impairment:** reduce dose or avoid. **Dose in hepatic impairment:** reduce dose or avoid.

### Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by deep IM injection.
- 3. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless to slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV injection over 3-5 minutes.
- 4. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

#### Monitoring

Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving initial dose, especially elderly patients or those of low bodyweight

| Measure                                       | Frequency            | Rationale                                                                                                                                           |
|-----------------------------------------------|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Pain                                          | At regular intervals | • To ensure therapeutic response.                                                                                                                   |
| Blood pressure, pulse<br>and respiratory rate |                      | • ↓BP, ↓pulse, ↑pulse, palpitations and respiratory depression can occur.                                                                           |
| Sedation                                      |                      | Can cause sedation.                                                                                                                                 |
| Monitor for side-<br>effects and toxicity     |                      | <ul> <li>May cause side-effects such as nausea and constipation, which may need treating.</li> <li>Signs of toxicity includes dysphoria.</li> </ul> |

| Additional information                    |                                                                                                                                                                                                                                                                                                                         |  |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Common and serious<br>undesirable effects | Common: Nausea and vomiting (particularly initially), constipation, dry mouth,<br>urticaria, pruritus, biliary spasm, ↑ or ↓pulse, hallucinations, euphoria,<br>drowsiness, withdrawal symptoms in opioid-dependent patients.<br>At higher doses: ↓BP, sedation, respiratory depression, muscle rigidity.               |  |
| Pharmacokinetics                          | Elimination half-life is 2 hours.                                                                                                                                                                                                                                                                                       |  |
| Significant<br>interactions               | <ul> <li>The following may îmeptazinol levels or effect (or îside-effects):<br/>antihistamines-sedating (îsedation), MAOIs (avoid combination and for 2<br/>weeks after stopping MAOI), moclobemide.</li> <li>Meptazinol may îlevels or effect (or îside-effects) of sodium oxybate (avoid<br/>combination).</li> </ul> |  |
| Action in case of<br>overdose             | Symptoms to watch for: <i>fSedation</i> , respiratory depression.<br>Antidote: Naloxone (see the Naloxone monograph), but may only partially<br>reverse toxicity.<br>Stop administration and give supportive therapy as appropriate.                                                                                    |  |
| Counselling                               | May cause drowsiness that may affect the ability to perform skilled tasks; if<br>affected do not drive or operate machinery, avoid alcoholic drink (the effects of<br>alcohol are enhanced).<br>Inform the patient of possible side-effects: see above.<br>Drink plenty of fluids to help avoid constipation.           |  |
|                                           |                                                                                                                                                                                                                                                                                                                         |  |

## **Bibliography**

SPC Meptid injections (accessed 13 July 2009).

# Meropenem

#### 500-mg, 1-g dry powder vials

- Meropenem trihydrate is a carbapenem beta-lactam antibacterial.
- It is used in the treatment of infections caused by susceptible Gram-negative and Gram-positive
  organisms including neutropenic sepsis, meningitis and infections in immune-compromised
  patients.

• Doses are expressed in terms of the base: Meropenem  $1g \cong 1.14 \, g$  of meropenem trihydrate.

## **Pre-treatment checks**

- Do not give if there is known hypersensitivity to any carbapenem antibacterial agent or previous immediate hypersensitivity reaction to penicillins or cephalosporins.
- Caution if predisposed to seizures (antiepileptic agents should be continued in those with known seizure disorders).

#### Biochemical tests

FBC LFTs Renal function: U, Cr, CrCl (or eGFR)

#### Dose

Standard dose: 500 mg by IV injection or infusion every 8 hours.

Severe infections: 1 g by IV injection or infusion every 8 hours.

Meningitis: 2 g by IV injection or infusion every 8 hours.

**Exacerbations of chronic lower respiratory tract infection in cystic fibrosis**: 2 g by IV injection or infusion every 8 hours.

Dose in renal impairment: adjusted according to creatinine clearance:<sup>1</sup>

- CrCl >20-50 mL/minute: 500 mg-2 g every 12 hours.
- CrCl 10-20 mL/minute: 500 mg-1 g every 12 hours or 500 mg every 8 hours.
- CrCl <10 mL/minute: 500 mg-1 g every 24 hours.

## Intravenous injection

#### Preparation and administration

- 1. Reconstitute each 500-mg vial with 10 mL WFI (use 20 mL for each 1-g vial).
- 2. Shake well until dissolved then allow to stand until solution is clear.
- 3. Withdraw the required dose.
- 4. Give by IV injection over 5 minutes

## Intermittent intravenous infusion

- 1. Reconstitute each 500-mg vial with 10 mL WFI (use 20 mL for each 1-g vial).
- 2. Shake well until dissolved then allow to stand until the solution is clear.
- Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually 50–200 mL NaCl 0.9%).
- 4. Give by IV infusion over 15-30 minutes.

# Mesna

#### 100 mg/mL solution in 4-mL and 10-mL ampoules

- Mesna is given systemically to protect the urinary tract from toxic urinary metabolites in patients being treated with oxazaphosphorine derivatives (ifosfamide, cyclophosphamide).
- The aim of treatment is to ensure that there are adequate levels of mesna in the bladder throughout the period that the toxic metabolites are present. Duration of mesna treatment should therefore equal that of the oxazaphosphorine treatment plus about 8–12 hours (the time it takes for the urinary metabolites to fall to non-toxic levels).
- · Mesna has also been used as a mucolytic in the management of some respiratory tract disorders.

## **Pre-treatment checks**

Patients receiving mesna for the prevention of ifosfamide-induced hemorrhagic cystitis should be adequately hydrated (at least 1 L of oral or IV fluid daily, prior to and during ifosfamide therapy).

#### Dose

In all cases be guided by the oncology team responsible for treating the patient.

**Intermittent injection or infusion**: the total dose of mesna is 60% (w/w) of the oxazaphosphorine dose in three divided doses; the first dose is concomitant with the oxazaphosphorine with the remaining doses after 4 and 8 hours.

Where ifosfamide is used as a 24-hour or long-term infusion: once administration of the ifosfamide dose is complete, a further 12-hour infusion of mesna is given at a dose of 60% (w/w) of the ifosfamide dose. Alternatively, the final 12-hour infusion of mesna may be replaced by three IV or oral doses, each of 20% (w/w) of the ifosfamide dose.

**Mucolytic (unlicensed):** the usual daily dose is 600 mg-1.2 g given by a nebuliser; it may also be given by direct endotracheal instillation.

## Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 3 minutes or as recommended by your oncology team.

## Intermittent intravenous infusion

#### Preparation and administration

- 1. Withdraw the required dose and add to a convenient volume of compatible infusion fluid (usually NaCl 0.9% or Gluc 5%) to give a solution containing approximately 20 mg/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 15–30 minutes or as recommended by your oncology team.

## **Continuous intravenous infusion**

#### Preparation and administration

- Withdraw the required dose and add to a convenient volume of compatible infusion fluid (usually NaCl 0.9% or Gluc 5%) to give a solution containing approximately 20 mg/mL. Mix well.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion as recommended by your oncology team.

## Oral (tablets are also available)

Measure the required dose and add to a flavoured soft drink (e.g. orange juice, cola). This mixture is stable when refrigerated in a sealed container for 24 hours.

# **Metaraminol**

#### 10 mg/mL solution in 1-mL ampoules

- Metaraminol tartrate is a sympathomimetic which exerts an inotropic effect and acts as a peripheral vasoconstrictor, thus *cardiac* output, peripheral resistance and BP.
- It is used to treat acute LBP where other measures have failed. It has also been used for its pressor action in hypotensive states such as those that may occur after spinal anaesthesia.

#### 544 | Metaraminol

 Doses are expressed in terms of the base: Metaraminol 5 mg ≈ 9.5 mg metaraminol tartrate.

#### **Pre-treatment checks**

- Do not use in pregnancy.
- Do not use with cyclopropane or halothane anaesthesia.
- Extreme caution in ↑BP (monitor BP and rate of flow frequently).
- Caution in coronary, mesenteric, or peripheral vascular thrombosis; following myocardial infarction, Prinzmetal's variant angina, hyperthyroidism, diabetes mellitus; hypoxia or hypercapnia; uncorrected hypovolaemia; elderly patients; a history of malaria; and cirrhosis.
- Hypoxia, hypercapnia, and acidosis should be corrected prior to or concurrently with administration of metaraminol (they may reduce the effectiveness and/or *îadverse* effects).
- Blood volume depletion should be corrected as fully as possible before therapy commences. In an
  emergency, it may be used as an adjunct to fluid volume replacement or as a temporary supportive
  measure to maintain coronary and cerebral artery perfusion until volume replacement therapy can
  be completed, but must not be used as sole therapy in hypovolaemic patients.
- Extravasation at injection site may cause necrosis.

#### Biochemical and other tests (not all are necessary in an emergency situation)

# Blood pressure

## TFTs

#### Dose

Avoid SC and IM injection (associated with local tissue necrosis and sloughing).

Standard dose: 15–100 mg by IV infusion, adjusted according to response.

**In an emergency**: 0.5–5 mg by IV injection, then 15–100 mg by IV infusion, adjusted according to response.

## Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection preferably into a large vein of the antecubital fossa or the thigh (veins in the ankle or hand should be avoided).

## **Continuous intravenous infusion**

- 1. Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually 15–100 mg in 500 mL; however, up to 500 mg per 500 mL has been used). Mix well.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion via a volumetric infusion device, adjusting rate to clinical response. Maximum effects are not immediately apparent: at least 10 minutes should elapse between dose increases. The possibility of a cumulative effect should be borne in mind. The patient should not be left unattended and the infusion flow rate must be closely monitored (severe \LBP may develop).

## Additional information

| Common and serious<br>undesirable effects | ↑BP, headache, ↑or↓ pulse, arrhythmias, peripheral ischaemia; fatal ventricular arrhythmia reported in Laennec's cirrhosis.                                                                                                                                                                       |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pharmacokinetics                          | Elimination half-life is not known.                                                                                                                                                                                                                                                               |
| Significant<br>interactions               | <ul> <li>The following may ↑metaraminol levels or effect (or ↑side-effects):<br/>MAOIs (risk of hypertensive crisis), moclobemide (risk of hypertensive crisis),<br/>rasagiline (avoid combination).</li> <li>Metaraminol may ↓levels or effect of guanethidine (↓hypotensive effect).</li> </ul> |
| Action in case of<br>overdose             | Reduce infusion rate or stop administration and give supportive therapy as appropriate.                                                                                                                                                                                                           |

#### 546 | Metaraminol | Methadone hydrochloride

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Methadone hydrochloride

#### 10 mg/mL solution in 1-mL, 2-mL, 3.5-mL and 5-mL ampoules

- Methadone hydrochloride is an opioid analgesic.
- It is used to treat moderate to severe pain.
- It is also used in the management of opioid withdrawal because withdrawal symptoms from methadone develop more slowly than with other opioids.

## **Pre-treatment checks**

- Do not use in acute respiratory depression, where there is a risk of paralytic ileus, in ↑intracranial
  pressure and in head injury, in comatose patients; in acute abdomen; delayed gastric emptying;
  chronic constipation; cor pulmonale; acute porphyria.
- Caution in ↓BP, shock, convulsive disorders, supraventricular tachycardias, atrial flutter, chronic
  obstructive pulmonary disease and acute asthma attack, obstructive or inflammatory bowel diseases, biliary tract diseases, alcoholism, prostatic hyperplasia, myasthenia gravis, hypothyroidism
  (reduce dose), adrenocortical insufficiency (reduce dose).
- Caution in toxic psychosis and pancreatitis.
- Ensure resuscitation equipment and naloxone are available.

#### Biochemical and other tests (not all are necessary in an every situation)

#### Blood pressure and pulse

LFTs

ECG in patients at risk of QT prolongation (if the dose is increased above 100 mg/day in any patient an ECG should be carried out before the increase and 7 days after)

Pain score Renal function: U, Cr, CrCl (or eGFR) Respiratory rate

#### Dose

**Moderate to severe pain**: 5–10 mg by IM or SC injection every 6–8 hours when necessary. If required for longer than 2 days then give by IM injection twice daily to avoid accumulation.

**Opioid dependence**: 10–20 mg by IM injection once daily. Increase the dose by 10–20 mg a day until there are no signs of withdrawal or toxicity (usual range 40–60 mg in 24 hours). Reduce the dose gradually to zero, usually as part of a managed regimen.

Dose in renal impairment: reduce dose or avoid.

Dose in hepatic impairment: reduce dose or avoid.

## Intramuscular injection (preferred route if repeated doses are to be given)

## Preparation and administration

- 1. Withdraw the required dose.
- Give by deep IM injection. Volumes >2 mL (20 mg) should be distributed between injection sites.
- 3. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

## **Subcutaneous injection**

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by SC injection.
- 3. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving initial dose, especially elderly patients or those of low bodyweight.

Stop administration<br>and give supportive therapy as appropriate.                                                                                                                                                                                                                                                                                                                                                        |  |
| Counselling                               | May cause drowsiness that may affect the ability to perform skilled tasks;<br>if affected do not drive or operate machinery, avoid alcoholic drink (the<br>effects of alcohol are enhanced).<br>Drink plenty of fluids to help avoid constipation use a laxative if required.                                                                                                                                                                                                                                                                  |  |

## Bibliography

SPC Methadone 10 mg/mL solution for injection, Wockhardt UK Ltd (accessed 3 March 2009).

# Methylprednisolone acetate

#### 40 mg/mL aqueous suspension in 1-mL, 2-mL and 3-mL vials

This preparation must not be confused with the combined preparation that includes lidocaine.

- Methylprednisolone acetate is a corticosteroid with mainly glucocorticoid activity.
- It is used in inflammatory conditions of the joints, particularly rheumatoid arthritis.
- It is used in the treatment of conditions for which systemic corticosteroid therapy is indicated (except adrenal-deficiency states). Deep IM injections have a depot effect and may provide cover for up to 2 weeks.
- It may also be given by intra-articular, intrasynovial or intralesional injection for various inflammatory conditions.

#### **Pre-treatment checks**

- · Avoid where systemic infection is present (unless specific therapy given).
- · Avoid live virus vaccines in those receiving immunosuppressive doses.
- May activate or exacerbate amoebiasis or strongyloidiasis (exclude before initiating a corticosteroid in those at risk or with suggestive symptoms). Fungal or viral ocular infections may also be exacerbated.
- Caution in patients predisposed to psychiatric reactions, including those who have previously suffered corticosteroid-induced psychosis, or who have a personal or family history of psychiatric disorders.

#### Intra-articular:

- Do not inject into unstable joints.
- · Do not give in the presence of active infection in or near joints.

#### Dose

**Intramuscular:** 40–120 mg. The dose depends on the severity of the condition and may be repeated as indicated by the patient's response and clinical condition. The effect of a single 80-mg injection may be expected to last approximately 2 weeks.

**Intra-articular or intrasynovial or intradermal injection:** large joints: up to 20–80 mg; medium joints: 10–40 mg; small joints: 4–10 mg; intra-bursal: 4–30 mg; intralesional: 20–60 mg depending on the size of the lesion (for large lesions the dose may be distributed by repeated local injections of 20–40 mg); tendon sheath: 4–30 mg.

In recurrent or chronic conditions, repeat doses may be necessary.

## Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- Give by IM injection deep into the upper outer quadrant of the gluteal muscle (avoid the deltoid). Use alternate sides for subsequent injections.

#### **Other routes**

- 1. Withdraw the required dose.
- 2. Inject into the affected area.

- In tenosynovitis care should be taken to inject into the tendon sheath rather than into the substance of the tendon.
- After intra-articular injections treatment failure is usually the result of not entering the joint space.

## Bibliography

SPC Depo-Medrone 40 mg/mL (accessed 12 July 2009).

# Methylprednisolone sodium succinate

#### 40-mg, 125-mg, 500-mg, 1-g and 2-g dry powder vials all with solvent (WFI)

- · Methylprednisolone sodium succinate is a corticosteroid with mainly glucocorticoid activity.
- It is used in the treatment of conditions for which systemic corticosteroid therapy is indicated.
- It is used parenterally when a rapid effect is required in emergencies, and also when the oral route is temporarily unavailable or inappropriate.
- Doses are expressed in terms of the base: Methylprednisolone 100 mg  $\cong$  133 mg methylprednisolone sodium succinate.

### **Pre-treatment checks**

- Do not use in the treatment of cerebral oedema associated with malaria.
- Avoid where systemic infection is present (unless specific therapy is given).
- · Avoid live virus vaccines in those receiving immunosuppressive doses.
- May activate or exacerbate amoebiasis or strongyloidiasis (exclude before initiating a corticosteroid in those at risk or with suggestive symptoms). Fungal or viral ocular infections may also be exacerbated.
- Caution in patients predisposed to psychiatric reactions, including those who have previously suffered corticosteroid-induced psychosis, or who have a personal or family history of psychiatric disorders.
- Rapid IV administration of large doses is associated with cardiovascular collapse.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Electrolytes: serum Na, K, Ca

#### Dose

**Standard dose:** depending on the indication, 10–500 mg given by IM injection or by IV injection or infusion. The dose depends on the severity of the condition and may be repeated as indicated by the patient's response and clinical condition.

Acute exacerbations of multiple sclerosis: 1 g daily for 3 days. Acute graft rejection reactions: 1 g daily for up to 3 days.

#### Intramuscular injection

#### Preparation and administration

- 1. Reconstitute with the diluent provided.
- 2. Withdraw the required dose.
- 3. Give by IM injection.

#### Intravenous injection (for doses up to 250 mg only)

#### Preparation and administration

- 1. Reconstitute each vial with the diluent provided.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration. Discard if present.
- 3. Give by IV injection over a minimum of 5 minutes.

## Intermittent intravenous infusion (for doses more than 250 mg)

- 1. Reconstitute each vial with the diluent provided.
- Withdraw the required dose and add to a suitable volume of compatible infusion solution (usually 100–250 mL NaCl 0.9%)

- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration. Discard if present.
- 4. Give by IV infusion over a minimum of 30 minutes.

| Action in case of overdose                | No known antidote but haemodialysis may be effective.<br>Give supportive therapy as appropriate. Following chronic overdose the<br>possibility of adrenal suppression should be considered.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |  |
| Counselling                               | Patients on long-term corticosteroid treatment should read and carry a Steroid Treatment Card.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |

## Bibliography

SPC Solu-Medrone (accessed 12 July 2009).

# Metoclopramide hydrochloride

#### 5 mg/mL solution in 2-mL and 20-mL ampoules

- Metoclopramide hydrochloride is a substituted benzamide that has prokinetic and antiemetic activity.
- It is used to treat nausea and vomiting of various aetiologies and to restore normal co-ordination and tone to the upper GI tract and it may also be given prior to various GI procedures. High-dose metoclopramide is now less commonly used for cytotoxic-induced nausea and vomiting.
- It may be given (unlicensed) by SC infusion in palliative care to treat nausea and vomiting and also to treat hiccups due to gastric distension.
- · Doses below are expressed in terms of metoclopramide hydrochloride.

#### **Pre-treatment checks**

- · Avoid in patients with phaeochromocytoma as it may induce an acute hypertensive response.
- Do not give during the first 3–4 days following operations such as pyloroplasty or gut anastomosis as vigorous muscular contractions may inhibit healing.
- Do not give in GI obstruction, perforation or haemorrhage.
- · Caution in epilepsy and patients treated with other centrally acting drugs.
- · Care should be taken in patients with a history of atopy (including asthma) or porphyria.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Bodyweight (if using in association with chemotherapy) LFTs Renal function: U, Cr, CrCl (or eGFR)

#### Dose

Because of the *frisk* of dystonic reactions (including oculogyric crises) in elderly and in young patients, particularly girls and young women, use of metoclopramide should be restricted to those situations for which there is no safer alternative. Lower doses should be used in these patient groups (maximum 500 micrograms/kg for high-dose therapy).

**Treatment of nausea and vomiting:** 10 mg (5 mg in young adults 15–19 years < 60 kg) by IV or IM injection three times a day.

**Diagnostic procedures:** 10–20 mg (10 mg in young adults 15–19 years) by IV or IM injection 5–10 minutes before procedure.

**Nausea and vomiting associated with cytotoxic chemotherapy:** 2–4 mg/kg by IV infusion before commencing chemotherapy followed by a continuous IV infusion of 3–5 mg/kg over 8–12 hours. Alternatively, give up to 2 mg/kg by IV infusion before commencing chemotherapy and repeat every 2 hours as necessary. Maximum dose by either method: 10 mg/kg in 24 hours.

**Dose in renal impairment:** avoid or reduce dose if CrCl <10 mL/minute (†risk of dystonic reactions). **Dose in hepatic impairment:** reduce dose.

## Intramuscular injection

- 1. Withdraw the required dose.
- 2. Give by IM injection.

## Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration (degradation is indicated by yellow discoloration) prior to administration and discard if present.
- 3. Give by slow IV injection over 2 minutes. Rapid administration may cause intense feelings of anxiety and restlessness which pass quickly and are then followed by drowsiness.

## Intermittent intravenous infusion (for cytotoxic chemotherapy only)

#### Preparation and administration

- 1. Withdraw the required dose and add to 50 mL of compatible infusion fluid.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration (degradation is indicated by yellow discoloration) prior to administration and discard if present.
- 3. Give by IV infusion over at least 15 minutes.

#### **Continuous intravenous infusion**

- 1. Withdraw the required dose and add to 500 mL of compatible infusion fluid. Mix well.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration (degradation is indicated by yellow discoloration) prior to administration and discard if present.
- 3. Give by IV infusion over 8-12 hours.

## Bibliography

SPC Maxalon injection (accessed 24 September 2008). SPC Metoclopramide 5 mg/mL injection, Hameln (accessed 24 August 2009).
# **Metoprolol tartrate**

#### 1 mg/mL injection solution in 5-mL ampoules

- · Metoprolol is a cardioselective beta-blocker.
- It is used parenterally for the early management of suspected acute myocardial infarction, within 12 hours of onset of chest pain.
- It may also be used in the management of tachyarrhythmias, particularly supraventricular tachyarrhythmias and to prevent or treat arrhythmias occurring during anaesthesia.

#### **Pre-treatment checks**

- Treatment should be avoided in sick sinus syndrome, ↓BP (use with caution in systolic BP <100 mmHg), heart block greater than first degree, ↓pulse (<45–50 bpm), cardiogenic shock and overt heart failure.
- · Use with caution in patients with a history of wheezing or asthma.

#### Biochemical and other tests (not all are necessary in an emergency situation)

LFTs

#### Dose

**Cardiac arrhythmias**: up to 5 mg by IV injection repeated at 5-minute intervals until a satisfactory response has been obtained. A total dose of 10–15 mg generally proves sufficient.

**During anaesthesia**: 2–4 mg IV at induction to prevent arrhythmias or to control arrhythmias developing during anaesthesia. Further injections of 2 mg may be given as required to a maximum overall dose of 10 mg.

**Myocardial infarction**: 5 mg by IV injection every 2 minutes to a maximum of 15 mg total dose as determined by BP and heart rate. Doses subsequent to the initial dose should not be given if systolic BP is <90 mmHg, the heart rate is <40 beats/minute and the P-Q time is >0.26 seconds, or if there is any aggravation of dyspnoea or cold sweating.

Oral therapy should commence 15 minutes after the last injection. Patients who fail to tolerate the full IV dose should be given a reduced oral dose when their condition permits.

Dose in hepatic impairment: reduce dose in severe impairment.

#### Intravenous injection

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection at a rate of 1-2 mg per minute.

#### 560 | Metoprolol tartrate | Metronidazole

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

#### Bibliography

SPC Betaloc IV injection (accessed 8 February 2009).

### **Metronidazole**

#### 5 mg/mL solution in 100-mL infusion bags

- Metronidazole is a synthetic, nitroimidazole-derivative antibacterial with activity against anaerobes, facultative anaerobes and protozoa.
- It is used in the treatment and prophylaxis of anaerobic infections and in the treatment of susceptible protozoal infections such as amoebiasis, giardiasis and trichomoniasis.

#### **Pre-treatment checks**

- · Avoid in acute porphyria.
- · Caution in hepatic impairment and hepatic encephalopathy.

#### **Biochemical tests**

LFTs FBC

#### Dose

**Anaerobic infections (if oral therapy is inappropriate):** 500 mg by IV infusion every 8 hours (usually for 7 days; for 10 days in antibiotic-associated colitis). Oral medication should be substituted as soon as is practical.

**Surgical prophylaxis (if oral or rectal administration is inappropriate):** 500 mg by IV infusion at induction, with up to three further doses of 500 mg given every 8 hours for high-risk procedures. Check local policies.

**Dose in hepatic encephalopathy:** 500 mg once daily - this is usually only when hepatic function is very poor, and particularly when renal function is also impaired.

#### Intermittent intravenous infusion

Preparation and administration

Metronidazole is incompatible with Gluc 10% and Hartmann's.

- 1. The infusion is pre-prepared for use and should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 2. Give by IV infusion at a rate of about 5 mL/minute (i.e. 500 mg over 20 minutes).

#### Bibliography

SPC Flagyl 500 mg/100 mL solution for infusion (accessed 1 April 2009).

# **Mexiletine hydrochloride**

#### 25 mg/mL solution in 10-mL ampoules

- Mexiletine hydrochloride is a class Ib antiarrhythmic with actions similar to those of lidocaine.
- · It has been used for the treatment of life-threatening ventricular arrhythmias.
- It is no longer marketed in the UK as toxicity is common even at therapeutic blood concentrations, but it is available from 'special-order' manufacturers or specialist-importing companies.

#### **Pre-treatment checks**

- Do not give in cardiogenic shock and in second- or third-degree AV block (unless the patient has a
  pacemaker).

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure and pulse ECG LFTs

# Dose (no longer licensed in UK; doses specified are previously licensed doses)

#### Loading doses:

- 1. Give 100-250 mg (4-10 mL) by slow IV injection at a maximum rate of 25 mg/minute.
- 2. Add 500 mg to 500 mL infusion fluid and give 250 mg (250 mL) by IV infusion over the first hour, then 250 mg (250 mL) over the next 2 hours.

**Maintenance infusion:** add 250 mg to 500 mL infusion fluid and give by IV infusion at an initial rate of 500 micrograms/minute (1 mL/minute) and adjust according to clinical response. Switch to oral therapy as soon as possible.

**Alternative method using combined IV and oral loading**: give 200 mg (4 mL) by slow IV injection at a maximum rate of 25 mg/minute. Give 400 mg orally on completion of the injection, then regular oral therapy thereafter.

Dose in renal impairment: adjusted according to creatinine clearance:<sup>1</sup>

- CrCl >20-50 mL/minute: dose as in normal renal function.
- CrCl 10-20 mL/minute: dose as in normal renal function.
- CrCl <10 mL/minute: 50-75% of normal dose and titrate according to response.

#### Intravenous injection (initial loading dose only)

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV injection at a maximum rate of 25 mg/minute (1 mL/minute). May be diluted with NaCl 0.9% or Gluc 5% to facilitate slow administration.

#### Intravenous infusion (subsequent doses)

- 1. Withdraw the required dose (see Dose above) and add to 500 mL NaCl 0.9% or Gluc 5%.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion via a volumetric infusion device at the rate specified above.
- 4. Prepare a fresh infusion every 8 hours if required.

# Micafungin

#### 50-mg and 100-mg dry powder vials

- Micafungin sodium is a semi-synthetic, echinocandin antifungal agent with properties similar to caspofungin.
- It is used in the treatment of invasive candidiasis and also for prophylaxis of candidal infection in
  patients who are to undergo stem cell transplantation or who are likely to develop neutropenia.
- · Doses are expressed in terms of micafungin base.

#### **Pre-treatment checks**

Do not give to patients with galactose intolerance, the Lapp lactase deficiency or glucose-galactose malabsorption (lactose is an excipient).

Biochemical and other tests (not all are necessary in an emergency situation)

 Bodyweight
 LFTs

 Electrolytes: serum Na, K, (consider Mg, Ca, PO<sub>4</sub>)
 Renal function: U, Cr

 FBC
 Fungal culture to identify causative organism, although therapy may be commenced before these results are known

#### Dose

**Invasive candidiasis**: adults >40 kg, 100 mg once daily (increased to 200 mg daily if inadequate response) for at least 14 days; adults  $\leq$ 40 kg, 2 mg/kg once daily (increased to 4 mg/kg daily if inadequate response) for at least 14 days.

**Oesophageal candidiasis where IV therapy is appropriate:** adults > 40 kg, 150 mg once daily;  $adults \le 40 \text{ kg}$ , 3 mg/kg once daily; for at least one week after resolution of symptoms.

**Prophylaxis of candidiasis in patients undergoing bone-marrow transplantation or who are expected to become neutropenic for over 10 days:** adults >40 kg, 50 mg once daily; adults ≤40 kg, 1 mg/kg once daily. Continue for at least 7 days after neutrophil count in desirable range.

**Dose in hepatic impairment:** use with caution in mild to moderate hepatic impairment; avoid in severe hepatic impairment—no information available.

#### Intermittent intravenous infusion

Protect from light after reconstitution and during infusion.

- Reconstitute each vial with 5 mL NaCl 0.9% or Gluc 5% by injecting the fluid slowly against the side of the inner wall of the vial to minimise foaming.
- Swirl gently to dissolve the contents (vigorous shaking will cause foaming) to give a solution containing 10 mg/mL (50-mg vial) or 20 mg/mL (100-mg vial).
- Withdraw the required dose and add to 100 mL NaCl 0.9% or Gluc 5%. Gently invert to disperse the diluted solution but **do not** agitate in order to avoid foaming.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Insert the infusion bag/bottle into a closable opaque bag to protect it from light (it is not necessary to cover the giving set).
- Give by IV infusion over 60 minutes.

| Technical information |                                                                                                                                                                                                                                            |  |  |

### Additional information

| Common and serious<br>undesirable effects | <ul> <li>Immediate: Anaphylaxis has been reported rarely.<br/>Injection/infusion-related:</li> <li>Too rapid administration: Rapid infusions can result in allergic reactions.</li> <li>Local: Injection-site pain, inflammation or thrombosis.</li> <li>Other: Headache, nausea, vomiting, diarrhoea, abdominal pain, rash, pyrexia, rigors, peripheral oedema.</li> </ul> |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pharmacokinetics                          | Elimination half-life is 10-17 hours.                                                                                                                                                                                                                                                                                                                                       |
| Significant interactions                  | No significant interactions.                                                                                                                                                                                                                                                                                                                                                |
| Action in case of overdose                | No antidote: give supportive therapy as appropriate. Micafungin is not dialysable.                                                                                                                                                                                                                                                                                          |
| Counselling                               | Warn patient to report any symptoms consistent with liver toxicity, e.g.<br>nausea, vomiting, loss of appetite, pain in upper stomach, yellowing of skin or<br>the whites of the eyes.                                                                                                                                                                                      |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

### Bibliography

SPC Mycamine 50 mg and 100 mg powder for solution for infusion (accessed 13 April 2009).

# Midazolam

#### 1 mg/mL solution in 2-mL and 5-mL ampoules

High-strength preparations:

#### 2 mg/mL solution in 5-mL ampoules

#### 5 mg/mL solution in 2-mL and 10-mL ampoules

- Midazolam hydrochloride is a benzodiazepine with anxiolytic and amnesic activity in addition to sedative and hypnotic properties.
- It is used as a short-acting sleep-inducing drug in anaesthesia, conscious sedation and for sedation in critical care units.
- The injection solution may be given (unlicensed) by buccal administration in the treatment of status epilepticus.
- Midazolam may also be given (unlicensed) by SC injection or infusion in palliative care to calm very restless patients.
- Doses are expressed in terms of the base: Midazolam  $1 \text{ mg} \cong 1.1 \text{ mg}$  midazolam hydrochloride.

#### NPSA Rapid Response Report (December 2008)

In order to reduce the risk of overdose with midazolam injection in adults the UK NPSA has stipulated that:

- Use of high-strength midazolam preparations is restricted to clinical areas/situations where its use has been risk-assessed.
- Other clinical areas should only routinely stock low-strength midazolam.
- Staff involved in sedation techniques must have the necessary skills.
- Flumazenil should be available wherever midazolam is used.

### Pre-treatment checks

- Avoid use for conscious sedation in patients with severe respiratory failure or acute respiratory depression.
- Caution in high-risk patients, e.g. >60 years old, chronically ill or debilitated closer monitoring will be required.

#### 568 | Midazolam

- · Caution in patients with myasthenia gravis.
- · Facilities for resuscitation should always be available when IV midazolam is administered.
- When midazolam and an opioid are used together, the opioid should be given first.

Biochemical and other tests (not all are necessary in an emergency situation)

Bodyweight (in certain indications) LFTs Renal function: U, Cr, CrCl (or eGFR)

#### Dose

**Conscious sedation in adults** <**60 years**: initial dose 2–2.5 mg by IV injection 5–10 minutes before the procedure. If required additional doses of 1 mg by IV injection may be given up to a maximum of 7.5 mg (usual total dose: 3.5–5 mg).

**Conscious sedation in adults**  $\geq$ **60 years/debilitated or chronically ill**: initial dose 0.5–1 mg by IV injection 5–10 minutes before the procedure. If required additional doses of 0.5–1 mg by IV injection may be given up to a maximum of 3.5 mg.

**Premedication in adults** <**60 years**: 1–2 mg by IV injection repeated as required or 70–100 micrograms/kg by deep IM injection. The IM injection should be given 20–60 minutes before induction.

**Premedication in adults**  $\geq$ **60 years/debilitated or chronically ill:** 0.5 mg by IV injection repeated as required; or 25–50 micrograms/kg by deep IM injection. The IM injection should be given 20–60 minutes before induction.

**Anaesthesia induction in adults** <**60 years**: 150–200 micrograms/kg (300–350 if no premedication) by IV injection.

Anaesthesia induction in adults  $\geq$ 60 years/debilitated or chronically ill: 50–150 micrograms/kg (150–300 if no premedication) by IV injection.

Sedative component in combined anaesthesia: 30-100 micrograms/kg by IV injection repeated as necessary; or 30-100 micrograms/kg/hour by continuous IV infusion. Use lower doses in adults  $\geq 60$  years and the debilitated or chronically ill.

Sedation in critical care: initially 30–300 micrograms/kg given in increments of 1–2.5 mg by IV injection every 2 minutes followed by a maintenance dose of 30–200 micrograms/kg/hour by continuous IV infusion.

Status epilepticus (unlicensed): 10 mg by buccal administration, repeated once if necessary.

**Dose in renal impairment:** a lower dose may be required; monitor carefully during continuous infusion.

Dose in hepatic impairment: a lower dose may be required.

#### Intravenous injection

Preparation and administration

Make sure that you have selected the correct strength of midazolam ampoule.

- 1. Withdraw the required dose.
- The solution should be clear and colourless to light yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV injection at a rate of approximately 1 mg per 30 seconds (dependent on individual age, weight and response).

#### Continuous intravenous infusion via syringe pump

Preparation and administration

Make sure that you have selected the correct strength of midazolam ampoule.

- Withdraw the required dose and dilute to a suitable volume in a syringe pump with NaCl 0.9% or Gluc 5%. (The recommended concentration for infusion in a critically ill adult patient is 1 mg/mL but it may be administered undiluted.)
- 2. Cap the syringe and mix well.
- 3. The solution should be clear and colourless to light yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion at a rate appropriate to indication. Adjust rate to clinical response.

#### Intramuscular injection (painful - use only if no other route is available)

Preparation and administration

Make sure that you have selected the correct strength of midazolam ampoule.

- 1. Withdraw the required dose.
- 2. Give by deep IM injection into a large muscle mass.

#### Buccal administration (unlicensed use in status epilepticus)

#### Preparation and administration

Make sure that you have selected the correct strength of midazolam ampoule (usually the 10 mg/2 mL strength is used).

- 1. Withdraw the required dose from the ampoule using a filter straw attached to a 2-mL oral syringe.
- 2. Remove the filter straw from the syringe.
- 3. Open the patient's lips and drip the midazolam solution into the buccal area of the mouth (between the cheek and gum of the lower jaw).
- 4. Once the dose has been given, hold the lips gently shut for 1-2 minutes to prevent leakage.

# Milrinone

#### 1 mg/mL solution in 10-mL ampoules

- Milrinone lactate is a phosphodiesterase type 3 inhibitor with positive inotropic and vasodilator activity.
- It is used for short-term management of heart failure unresponsive to other treatments, including low-output states following heart surgery.
- Doses are expressed in terms of the base: Milrinone 1 mg ≡ 1.43 mg milrinone lactate.

#### **Pre-treatment checks**

Use with caution in heart failure associated with hypertrophic cardiomyopathy, stenotic or obstructive valvular disease or other outlet obstruction.

Biochemical and other tests (not all are necessary in an emergency situation)

Bodyweight Electrolytes: serum K Renal function: U, Cr, CrCl (or eGFR)

#### Dose

Loading dose: 50 micrograms/kg usually followed by maintenance infusion.

**Maintenance infusion**: at 0.375–0.75 microgram/kg/minute according to haemodynamic and clinical response.

**Dose in renal impairment**: renal impairment significantly reduces the terminal elimination halflife of milrinone. The following are maximum recommended maintenance infusion rates adjusted according to creatinine clearance:

- CrCl 50 mL/minute: 0.43 microgram/kg/minute.
- CrCl 40 mL/minute: 0.38 microgram/kg/minute.
- CrCl 30 mL/minute: 0.33 microgram/kg/minute.
- CrCl 20 mL/minute: 0.28 microgram/kg/minute.
- CrCl 10 mL/minute: 0.23 microgram/kg/minute.
- CrCl 5 mL/minute: 0.20 microgram/kg/minute.

#### Intravenous injection (loading dose only)

- 1. Withdraw the required dose.
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 10 minutes. May be diluted to 10 mL with NaCl 0.9% or Gluc 5% to facilitate slow administration.

#### 572 | Milrinone

#### Continuous intravenous infusion via a syringe pump

Preparation of a 200 micrograms/mL solution

- 1. Withdraw 10 mg (10 mL) of injection and make up to 50 mL in a syringe pump with NaCl 0.9% or Gluc 5% fluid.
- 2. Cap the syringe and mix well to give a solution containing 200 micrograms/mL.
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

Give by IV infusion via a syringe pump at an initial rate of 0.375 microgram/kg/minute. Adjust the dose according to clinical response. Prepare a fresh syringe every 24 hours.

```
Calculation of infusion rate:
```

```
Infusion \ rate \ (mL/hour) = \frac{Weight \ (kg) \times required \ rate \ (micrograms/minute) \times 60}{Concentration \ of \ prepared \ infusion \ (micrograms/mL)}
```

See Table M1 below for a dosage chart detailing pre-calculated infusion rates for each bodyweight using a 200 micrograms/mL solution.

**Table M1**Milrinone rate of infusion using milrinone 10 mg (10 mL) made up to50 mL in a 50-mL syringe pump, i.e. 200 micrograms/mL)

# **Morphine sulfate**

#### 10 mg/mL, 15 mg/mL, 20 mg/mL, 30 mg/mL solution in 1-mL and 2-mL ampoules 1 mg/mL solution in 10-mL pre-filled syringe; 1 mg/mL and 2 mg/mL solution in 50-mL vials

- Morphine sulfate is a potent opioid analgesic.
- It is used parenterally for the treatment of moderate to severe pain; relief of dyspnoea of left ventricular failure and pulmonary oedema; pre-operative and postoperative care.
- Morphine may also be given by SC infusion to control pain in palliative care.
- · Doses below are expressed in terms of morphine sulfate.

#### **Pre-treatment checks**

- Do not use in acute respiratory depression, where there is a risk of paralytic ileus, in ↑intracranial
  pressure and in head injury, in comatose patients; in acute abdomen; delayed gastric emptying;
  chronic constipation; acute porphyria; heart failure secondary to chronic lung disease; and
  phaeochromocytoma.
- Caution in JBP, shock, convulsive disorders, cardiac arrhythmias, e.g. supraventricular tachycardias and atrial flutter, chronic obstructive pulmonary disease and acute asthma attack, obstructive or inflammatory bowel diseases, biliary tract diseases, alcoholism, prostatic hyperplasia, myasthenia gravis, hypothyroidism (reduce dose), adrenocortical insufficiency (reduce dose), pancreatitis, severe cor pulmonale.
- Ensure resuscitation equipment and naloxone are available especially for IV administration.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure and pulse LFTs Pain score Renal function: U, Cr, CrCl (or eGFR) Respiratory rate

#### Dose

Note: Doses above those stated must not be given to opioid naive patients.

**Acute pain**: 10 mg by SC or IM injection or 2.5 mg by slow IV injection every 4 hours when required. Halve the initial dose in elderly or frail patients. Doses may be given more frequently during initial titration of requirements but the patient must be very closely monitored.

**Chronic pain**: 5–20 mg by SC or IM injection or 2.5–15 mg by slow IV injection regularly every 4 hours adjusted according to requirements. Initial dose is dependent on previous opioid exposure – see below.

#### Approximate equivalents for patients switched from oral to parenteral

10 mg orally every 4 hours (or 60 mg daily as oral modified release) is equivalent to:

- 5 mg by IM injection every 4 hours (total 30 mg daily)
- 5 mg by SC injection every 4 hours (total 30 mg daily)
- 2.5 mg by IV injection every 4 hours (total 15 mg daily)

Alternatively, give 1–5 mg every hour by IV infusion adjusted according to requirements. Similar doses have been given by SC infusion (unlicensed).

Premedication: up to 10 mg by SC or IM injection 60-90 minutes before procedure.

#### 576 | Morphine sulfate

**Myocardial infarction**: 10 mg by slow IV injection followed by a further 5–10 mg if necessary (halve dose in elderly or frail patients).

Acute pulmonary oedema: 5-10 mg by slow IV injection.

Patient-controlled analgesia (PCA): consult local hospital protocol.

Dose in hepatic impairment: reduce dose or avoid (may precipitate coma).

Dose in renal impairment: reduce dose or avoid (prolonged effect, and ↑cerebral sensitivity).

#### Subcutaneous injection (not suitable for oedematous patients)

#### Preparation and administration

Check that you have selected the correct strength of ampoule. High-strength ampoules are available for use in PCA and palliative care. These are not suitable for use in acute situations.

- 1. Withdraw the required dose.
- 2. Give by SC injection.
- 3. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving initial dose, especially elderly patients or those of low bodyweight.

#### Intramuscular injection

#### Preparation and administration

Check that you have selected the correct strength of ampoule. High-strength ampoules are available for use in PCA and palliative care. These are not suitable for use in acute situations.

- 1. Withdraw the required dose.
- 2. Give by IM injection.
- 3. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving initial dose, especially elderly patients or those of low bodyweight.

#### Intravenous injection

Preparation and administration

Check that you have selected the correct strength of ampoule. High-strength ampoules are available for use in PCA and palliative care. These are not suitable for use in acute situations.

- 1. Withdraw the required dose. It may be further diluted with NaCl 0.9% or Gluc 5% to facilitate slow administration (10 mg is often diluted to 10 mL).
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by slow IV injection at a maximum rate of 2 mg/minute (1 mg/minute in opioid naive patients).
- 4. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving initial dose, especially elderly patients or those of low bodyweight.

#### Patient-controlled analgesia<sup>1</sup>

Preparation and administration

Strength used may vary depending on local policies.

- 1. Make 50 mg morphine sulfate up to 50 mL with NaCl 0.9% in a PCA syringe to give a solution containing 1 mg/mL or use a pre-prepared solution.
- 2. Cap the syringe and mix well.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. The usual setting for the PCA device is to deliver a 1-mg bolus with a 5-minute lock-out period. Lower doses are used in patients with renal failure.

#### **Continuous intravenous infusion**

- 1. Withdraw the required dose and further dilute with NaCl 0.9% or other compatible diluent to a convenient volume.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by continuous IV infusion via a volumetric infusion device.

| Excipients                  | Some products contain sulfites (may cause hypersensitivity reactions).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |  |
| Storage                     | Store below $25^\circ\text{C}$ in original packaging. Controlled Drug.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |  |
| Stability after preparation | From a microbiological point of view, should be used immediately; however, prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |

### Monitoring

Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving initial dose, especially elderly patients or those of low bodyweight.

# Morphine tartrate with cyclizine (Cyclimorph)

### Cyclimorph 10 solution in 1-mL ampoules (≅ morphine tartrate 10 mg plus cyclizine tartrate 40 mg)

### Cyclimorph 15 solution in 1-mL ampoules (≅ morphine tartrate 15 mg plus cyclizine tartrate 40 mg)

- Cyclimorph injection contains the potent opioid analgesic morphine tartrate combined with the antiemetic antihistamine cyclizine tartrate.
- It is used to treat moderate to severe pain where an additional antiemetic effect is helpful.
- · Cyclimorph is intended for short-term use only and is not recommended for palliative care.
- Doses below are quoted in millilitres of either of the combined products: Cyclizine tartrate 40 mg  $\cong$  50 mg cyclizine lactate in effect.

#### **Pre-treatment checks**

- Do not use in acute respiratory depression, where there is a risk of paralytic ileus, in ↑intracranial
  pressure and in head injury, in comatose patients; in acute abdomen; delayed gastric emptying;
  chronic constipation; acute porphyria; heart failure secondary to chronic lung disease; and
  phaeochromocytoma.
- Caution in JBP, shock, convulsive disorders, cardiac arrhythmias, e.g. supraventricular tachycardias and atrial flutter, chronic obstructive pulmonary disease and acute asthma attack, obstructive

#### 580 | Morphine tartrate with cyclizine

or inflammatory bowel diseases, biliary tract diseases, alcoholism, prostatic hyperplasia, myasthenia gravis, hypothyroidism (reduce dose), adrenocortical insufficiency (reduce dose), pancreatitis, severe cor pulmonale.

- Caution also in severe heart failure and myocardial infarction as cyclizine lowers cardiac output and counteract the haemodynamic benefits of opioids.
- Ensure resuscitation equipment and naloxone are available especially for IV administration.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure and pulse LFTs Pain score Renal function: U, Cr, CrCl (or eGFR) Respiratory rate

#### Dose

**Moderate to severe pain**: 1 mL (i.e. 10 or 15 mg of morphine tartrate) by SC, IM, or IV injection every 4 hours as required up to a maximum three doses in 24 hours. Use reduced doses in elderly or frail patients.

**Dose in hepatic impairment:** reduce the dose or avoid (may precipitate coma). **Dose in renal impairment:** avoid if CrCl <20 mL/minute.

#### **Subcutaneous injection**

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by SC injection.

#### Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.
- 3. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving initial dose, especially elderly patients or those of low bodyweight.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose. May be diluted with an equal volume of WFI to facilitate slow administration.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV injection at a rate of 2 mg/minute of morphine (1 mg/minute in opioid naive patients).
- 4. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving initial dose, especially elderly patients or those of low bodyweight.

# Mycophenolate mofetil

#### 500-mg dry powder vials

- Mycophenolate mofetil hydrochloride is an immunosuppressant derived from *Penicillium stoloni-ferum*. It is a reversible inhibitor of inosine monophosphate dehydrogenase and inhibits purine synthesis with potent effects on both T- and B-lymphocytes.
- It is given with other immunosuppressants for the prevention of graft rejection and it has also been used (unlicensed) in various autoimmune diseases.
- The parenteral form is used when oral therapy is not possible and is licensed for up to 14 days use.
- Doses are expressed in terms of mycophenolate mofetil: Mycophenolate mofetil 1 g ≅ 1.08 g mycophenolate mofetil hydrochloride.

#### **Pre-treatment checks**

- · Do not give in pregnancy or breast feeding.
- Caution in elderly patients (*\risk of infection, GI haemorrhage and pulmonary oedema*), active serious GI disease (risk of haemorrhage, ulceration and perforation) and delayed graft function.

#### Biochemical and other tests

Blood glucose Blood pressure and pulse Electrolytes: serum K, Mg, Ca, PO<sub>4</sub> Lipid profile Renal function: U, Cr, CrCl (or eGFR)

#### Dose

The initial dose of parenteral therapy should be given within 24 hours of transplantation.

Renal transplantation: 1 g by IV infusion twice daily.

**Hepatic transplantation**: 1g by IV infusion twice daily for the first 4 days following hepatic transplantation, followed by oral therapy (1.5g twice daily mycophenolate mofetil) as soon as it can be tolerated.

**Dose in renal impairment:** outside the immediate post-transplantation period doses >1 g twice daily of mycophenolate mofetil should be avoided if CrCl <20 mL/minute.

#### Intermittent intravenous infusion

Preparation and administration

See Special handling and Spillage below. Mycophenolate mofetil is incompatible with NaCl 0.9%, Hartmann's, Ringer's.

- 1. Reconstitute each 500-mg vial with 14 mL Gluc 5% and shake gently to give a solution containing 500 mg/15 mL.
- Withdraw the required dose and add to a suitable volume of Gluc 5% to give a solution containing approximately 6 mg/mL (i.e. add each 1-g dose to 140 mL Gluc 5%; add each 1.5-g dose to 210 mL Gluc 5%).
- 3. The solution should be clear and colourless to slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 2 hours.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

### **Bibliography**

SPC Cellcept 500 mg powder (accessed 5 March 2010).

# Naloxone hydrochloride

### 400 micrograms/mL solution in 1-mL ampoules; 1-mL, 2-mL and 5-mL pre-filled syringes

#### 1 mg/mL solution in 2-mL pre-filled syringe

- Naloxone hydrochloride is a specific opioid antagonist that acts competitively at opioid receptors.
- It is used in the treatment of respiratory depression induced by opioids, partial opioid agonists or in suspected opioid overdose.
- It is also used to treat asphyxia in neonates after the administration of opioid analgesics to the mother during labour.
- Naloxone has been used (unlicensed) to treat cholestatic pruritus.
- It has also been given (unlicensed) to treat severe constipation resulting from opioid use in critical care.
- · Naloxone has also been given by endotracheal, intranasal and intraosseous routes (all unlicensed).

#### **Pre-treatment checks**

- Caution in cardiovascular disease, it has caused serious adverse effects, e.g. ventricular tachycardia and fibrillation in postoperative patients.
- Caution in patients who may be physically dependent on opioids as this may precipitate severe withdrawal symptoms.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Bodyweight     | Pulse            |
|----------------|------------------|
| Blood pressure | Respiratory rate |

#### Dose

Naloxone onset of action: 1–2 minutes following IV injection; 2–5 minutes following SC or IM injection. It is rapidly metabolised in the liver.

**Opioid overdose (known or suspected):** 400 micrograms – 2 mg by IV injection repeated at intervals of 2–3 minutes to the required degree of reversal. Maximum dose 10 mg. If respiratory function does not improve, reconsider diagnosis. If the IV route is unavailable, may be given by IM or SC injection but onset is slower.

**Continuous IV infusion**: for opioid overdose use the syringe pump method below. The rate is set to deliver 60% of the initial effective IV injection dose over 1 hour and adjusted according to response. **Postoperative use:** 100–200 micrograms (1.5–3 micrograms/kg) by IV injection. Titrate the dose to patient response. Allow a full 2 minutes to elapse between 100-microgram increments. Be aware that analgesia will also be reversed.

**Cholestatic pruritus (unlicensed):** 400 micrograms by IV injection followed by 0.2 micrograms/ kg/minute by IV infusion.

**Severe constipation due to opioid use in critical care (unlicensed):** 4 mg via nasogastric tube. Warning: this can be *very* effective!

#### Intravenous injection (preferred route)

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection into a large vein.

# Continuous intravenous infusion via a syringe pump (unlicensed concentration)

#### Preparation and administration

- 1. Withdraw 4 mg and make up to 20 mL with NaCl 0.9% in a syringe pump
- 2. Cap the syringe and mix well to give a solution containing 200 micrograms/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion. Rate is set to deliver 60% of the initial effective IV injection dose over 1 hour and adjusted according to response. Be aware that some opioids may be relatively long-acting.
- 5. Prepare a fresh syringe at least every 24 hours if necessary.

#### Continuous intravenous infusion (large volume infusion)

#### Preparation and administration

- 1. Withdraw 2 mg of naloxone and add to 500 mL NaCl 0.9% or Gluc 5%.
- 2. Mix well to give a solution containing 4 micrograms/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion. Adjust the rate according to clinical response.
- 5. Prepare a fresh infusion at least every 24 hours if necessary.

#### Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

#### **Subcutaneous injection**

- 1. Withdraw the required dose.
- 2. Give by SC injection.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

#### **Bibliography**

SPC Naloxone injection (accessed 30 March 2010). SPC Miniject Naloxone (accessed 30 March 2010).

# Nandrolone

#### 50 mg/mL solution in ampoule or disposable syringe

- · Nandrolone decanoate is an anabolic steroid with some androgenic properties.
- It is licensed for use in treating osteoporosis in postmenopausal women, but its use has been superseded.
- It has been used to *\[\]lean body mass in various conditions where muscle wasting may occur such as debilitating illness, pre-dialysis chronic renal impairment and HIV-associated wasting. It has also been used to treat aplastic anaemia and anaemia of chronic renal failure (all unlicensed).*

#### **Pre-treatment checks**

- · Do not use in patients with peanut allergy as the injection contains arachis oil.
- Do not use in patients with an allergy to soya.
- Avoid in porphyria.
- · Avoid in known or suspected carcinoma of prostate or mammary carcinoma in the male.
- Avoid in patients with skeletal metastases, since anabolic steroids may cause ↑Ca and hypercalciuria in these patients.

#### Biochemical and other tests

Baseline prothrombin time Electrolytes: serum Na, K, Ca, PO<sub>4</sub> LFTs Lipids: baseline cholesterol Renal function: U, Cr, CrCl (or eGFR)

#### Dose

Osteoporosis: 50 mg every 3 weeks.

As an anabolic steroid in debilitating illness (unlicensed): 25–100 mg every 3–4 weeks has been used.

In anaemia of chronic renal failure (unlicensed): female patients have received 50–100 mg once weekly; male patients have received 100–200 mg once weekly.

#### Intramuscular injection

Contains arachis oil - should not be given in peanut allergy.

- 1. Withdraw the required dose.
- 2. Give by deep IM injection.

#### 590 | Nandrolone

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

#### **Bibliography**

SPC Deca-Durabolin 50 mg/mL (accessed 2 February 2009).

# Natalizumab

#### 20 mg/mL solution in 15-mL vials

- · Natalizumab is an alpha-4 integrin-specific humanised monoclonal antibody.
- It is used as monotherapy to reduce the frequency of clinical exacerbations, and delay the
  accumulation of physical disability, in patients with highly active relapsing-remitting forms of
  multiple sclerosis.
- As there is *\risk* of progressive multifocal leucoencephalopathy (PML; an opportunistic viral
  infection of the brain that usually leads to death or severe disability), its availability is restricted
  and its use limited to patients who have had an inadequate response to, or are unable to tolerate,
  other therapies.
- In the USA all doctors, pharmacies, infusion centres and patients must be registered with the TOUCH Prescribing Program before they can use or receive the drug (more information at www. tysabri.com).
- Continued therapy must be carefully reconsidered in any patients showing no evidence of therapeutic benefit beyond 6 months.

#### **Pre-treatment checks**

- Do not use in PML (a recent usually within 3 months MRI scan should be available), active
  infection (see notes above), concomitantly with interferon beta or glatiramer acetate, in
  immunosuppression, in active malignancies and pregnancy or breast feeding.
- · Resources for the management of hypersensitivity reactions and access to MRI should be available.

#### 592 | Natalizumab

#### Biochemical and other tests

FBC (there should be no signs of neutropenia before commencement and no evidence that the patient is immunocompromised) LFTs

### Dose

Standard dose: 300 mg by IV infusion every 4 weeks.

#### Intravenous infusion through a dedicated line

#### Preparation and administration

- 1. Inspect the vial contents prior to use. The solution should be clear and colourless to slightly opalescent. Discard if particulate matter or discoloration is present.
- 2. Withdraw the required dose, i.e. 300 mg (15 mL) and add to 100 mL NaCl 0.9%.
- 3. Invert the solution gently (do not shake) to mix completely.
- 4. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by IV infusion over 1 hour at a rate of approximately 2 mL/minute.
- 6. After the infusion is complete, flush the line with NaCl 0.9%.
- 7. Observe the patient (see monitoring below).

# **Neostigmine metilsulfate** (neostigmine methylsulfate)

#### 2.5 mg/mL solution 1-mL ampoules

- · Neostigmine is a compound with anticholinesterase activity that prolongs and intensifies the actions of acetylcholine.
- It is used to treat myasthenia gravis and as an antagonist to non-depolarising neuromuscular blockade. It has also been used to treat paralytic ileus, postoperative urinary retention and paroxysmal SVT.

## **Pre-treatment checks**

- · Do not give to patients with mechanical obstruction of intestinal or urinary tract or patients with peritonitis.
- Use with caution in patients with bronchial asthma, ↓pulse, cardiac arrhythmias, epilepsy, recent coronary occlusion, hyperthyroidism, peptic ulcer, vagotonia or parkinsonism.

#### Biochemical and other tests

Bodyweight (if using for reversal of non-depolarising neuromuscular blockade) Pulse

#### Dose

### For existing myasthenia gravis patients switched from maintenance to parenteral dosing:

Neostigmine bromide 15 mg orally  $\cong$  neostigmine metilsulfate 1–1.5 mg by IM or SC injection.

Myasthenia gravis: 1-2.5 mg by IM or SC injection at periodic intervals throughout the day (each dose will last 2-4 hours). The usual total daily dose is 5-20 mg but some patients may require more. Reversal of non-depolarising neuromuscular blockade: a single dose of 50-70 micrograms/ kg (maximum dose 5 mg) by IV injection after or with glycopyrronium or atropine (in ↓pulse, the pulse rate should be increased to 80 bpm before administering neostigmine).

Other indications: 0.5-2.5 mg by IM or SC injection.

Dose in renal impairment: adjusted according to creatinine clearance:1

- CrCl >20-50 mL/minute: 50-100% of normal dose.
- CrCl 10-20 mL/minute: 50-100% of normal dose.
- CrCl <10 mL/minute: 50-100% of normal dose.

# Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

# **Subcutaneous injection**

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by SC injection.

## Intravenous injection

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV injection over 1 minute.

# **Bibliography**

SPC Neostigmine Metilsulphate BP (accessed 30 March 2010).

# Nimodipine

#### 200 micrograms/mL solution in 50-mL (10 mg) vials

- · Nimodipine is a calcium-channel blocker acting primarily on cerebral blood vessels.
- It is used in treatment of aneurismal subarachnoid haemorrhage. Efficacy and safety have not been
  assessed in traumatic subarachnoid haemorrhage.
- Nimodipine infusion contains 23.7% ethanol by volume.
- A 250-mL average daily dose supplies 50 g ethanol  $\cong$  6 units (1 UK unit = 8 g).

## **Pre-treatment checks**

- Avoid within 1 month of ACS.
- · Do not use concurrently with oral nimodipine.
- Caution in cerebral oedema, ↑intracranial pressure, ↓BP, cirrhosis, renal disease.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Blood pressure            | LFTs                                  |
|---------------------------|---------------------------------------|
| Bodyweight                | Renal function: U, Cr, CrCl (or eGFR) |
| Electrolytes: serum Na, K |                                       |

### Dose

**Standard dose for patients** > **70 kg with stable BP:** 1 mg/hour (5 mL/hour) by IV infusion via a central line for the first 2 hours; if tolerated, increase to 2 mg/hour (10 mL/hour).

**Standard dose for patients** < **70 kg or with unstable BP:** 0.5 mg/hour (2.5 mL/hour) or less by IV infusion via a central line for the first 2 hours; if tolerated, increase gradually to 2 mg/hour (10 mL/hour).

**Duration of treatment:** treat for at least 5 days up to a maximum of 14 days. Continue for at least 5 days after neurological surgery. Where treatment is sequential with oral nimodipine, the total course should not exceed 21 days.

# Intravenous infusion via central line

Preparation and administration

Use only the infusion container and the infusion line provided by the manufacturer. Protect the infusion and giving set from direct sunlight.

- 1. Attach the infusion line provided by the manufacturer to the vial and prime the line. Do not use other lines, or other infusion containers.
- The solution should be clear and yellow in colour. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Attach the proximal end of the infusion line to a three-way tap such that a second infusion may run simultaneously into the central line.
- 4. The co-infusion must be set to run at 40 mL/hour (see Y-site below for suitable solutions).
- 5. Give nimodipine by IV infusion at the initial rate specified under Dose above and increase the rate as tolerated.
- 6. Protect the infusion and giving set from direct sunlight. The drug is stable in diffuse daylight and artificial light for up to 10 hours. Prepare a fresh infusion if required once 10 hours has elapsed.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Nimotop 0.02% solution for infusion (accessed 30 March 2010).

# Noradrenaline acid tartrate (norepinephrine bitartrate)

## 1 mg/mL (as base) solution in 2-mL, 4-mL and 20-mL ampoules

- Noradrenaline acid tartrate is an extremely potent peripheral vasoconstrictor used as an emergency measure in the restoration of BP in acute hypotension, usually in critical care.
- Ampoules are labelled in terms of the acid tartrate, but doses are expressed in terms of the base: Noradrenaline 1 mg ≅ 2 mg noradrenaline acid tartrate.

## **Pre-treatment checks**

• An inadequate circulating blood volume should be restored prior to treatment with noradrenaline.

Extreme caution in patients with:

- Coronary, mesenteric or peripheral vascular thrombosis; noradrenaline may extend the area of infarction.
- ↑BP following MI and in patients with Prinzmetal's variant angina.
- Hyperthyroidism, diabetes mellitus.
- Hypoxia or hypercapnia.

#### Biochemical and other tests

Electrolytes: serum Na, K Renal function: U, Cr, CrCl (or eGFR)

## Dose

Dosing regimens in the literature vary and may include weight-adjusted dosing.

There is a wide inter-individual variation in response and titration to response is fundamental. This is an example of a simple regimen:

- Initially 8-12 micrograms/minute adjusted according to BP response.
- Average maintenance dose is 2-4 micrograms/minute.
- Do not be stop suddenly withdraw gradually to avoid ↓BP.

# Continuous intravenous infusion via syringe pump

Infusion into a peripheral vein is not recommended owing to the high risk of extravasation and tissue necrosis.

#### Preparation of a 40 micrograms/mL solution

(Higher strength solutions using, e.g. 4 mg, 8 mg or 16 mg noradrenaline base may be prepared).

- 1. Make 2 mg (2 mL) up to 50 mL in a syringe pump with Gluc 5% to give a solution containing 40 micrograms/mL (as base).
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

- Give by IV infusion via a central venous catheter adjusting rate to clinical response, e.g. using a 40 micrograms/mL solution, an initial rate of 8–12 micrograms/minute equates to 12–18 mL/hour.
- 2. Prepare a fresh infusion every 24 hours. Discard if a brown colour or precipitate develops.

# **Bibliography**

SPC Noradrenaline (Norepinephrine) 1:1000 or Levophed (Hospira UK Ltd) (accessed 30 May 2009).

# Norethisterone enantate

#### 200 mg/mL oily solution in 1-mL ampoules

- · Norethisterone enantate is a progestogen formulated as a depot injection.
- It is given IM as an oily injection to provide short-term interim contraception.

# **Pre-treatment checks**

- Do not give in history of undiagnosed vaginal bleeding, or of breast or endometrial cancer (within the last 5 years; can be considered if incidence was >5 years ago with no current evidence of disease and non-hormonal methods of contraception are unacceptable).
- Contraindicated in women with a history of idiopathic jaundice, pruritus, herpes gestationis or deterioration of otosclerosis during pregnancy; in Dubin–Johnson and Rotor syndromes; in severe diabetes with vascular complications; in patients with <sup>↑</sup>BP, current thromboembolic disease (or in periods of high risk of thromboembolic disease, e.g. immobilisation or surgery).
- Patients with a history of diabetes should be carefully monitored during treatment, as a reduction in glucose tolerance may occur.
- Do not give during pregnancy.

#### 602 | Norethisterone enantate

#### Biochemical and other tests

FBC – contraindicated in sickle-cell anaemia LFTs Lipid profile

#### Dose

**Standard dose**: 200 mg by IM injection within first 5 days of cycle (the first day of menstruation counting as day 1); or immediately after delivery or abortion (so that no possibility for pregnancy exists). It may be repeated once after 8 weeks.

# Intramuscular injection

- 1. Immerse the ampoule in warm water before injection to reduce the viscosity, making it easier to inject.
- 2. Withdraw the 1 mL dose from the ampoule.
- 3. The injection requires significant force to administer due to its oily nature: firmly attach at least a medium-bore needle to the syringe before administration.
- 4. Give very slowly by deep IM injection into the gluteal muscle (coughing, dyspnoea and circulatory irregularities have been reported on administration, which can all be minimised by very slow administration).

| <b>Technical inform</b>                                                    | ation                                                           |                                                                                                                                                                                                                                                                                                                                     |  |

# Octreotide

#### 50, 100, 200, 500 micrograms/mL solution in 1-mL ampoules 200 micrograms/mL solution in 5-mL vials 10-mg, 20-mg and 30-mg dry powder vials

- Octreotide acetate is a synthetic polypeptide analogue of somatostatin with similar properties but a longer duration of action.
- It is used for the symptomatic management of neuroendocrine tumours (GEP tumours) such as carcinoid tumours, VIPomas and glucagonomas.
- It is also used in the treatment of acromegaly and the prevention of complications after pancreatic surgery, and in other disorders including variceal haemorrhage, reduction of intestinal secretions and HIV-associated diarrhoea.
- Octreotide may also be given (unlicensed) by SC infusion in palliative care to reduce intestinal secretions and vomiting.
- Doses are expressed as octreotide base.

### **Pre-treatment checks**

A test dose of 50–100 micrograms SC octreotide if commencing depot injections in patients with no previous exposure to octreotide.

#### Biochemical and other tests

Blood glucose Electrolytes: serum Zn (if receiving TPN) LFTs TFTs (if to be long term)

#### Dose

Give all doses between meals or before bedtime to reduce flatulence, abdominal pain and bloating.

**Neuroendocrine tumours:** initially 50 micrograms once or twice daily by SC injection gradually increased to 100–200 micrograms three times daily according to clinical response (exceptionally higher doses may be used). If a rapid response is required, e.g. carcinoid crises, the initial dose can be given by IV injection.

Sandostatin LAR: for patients whose symptoms are adequately controlled by SC injection, initially 20 mg Sandostatin LAR by IM injection every 4 weeks for 3 months, increasing to a maximum of 30 mg every 4 weeks if symptoms are only partially controlled. SC octreotide should be continued at the previously effective dose for 2 weeks after the first depot injection.

**Acromegaly:** initially 100–200 micrograms three times daily by SC injection. Discontinue if there is no improvement in 3 months.

*Sandostatin LAR:* patients new to octreotide must receive a test dose of 50–100 micrograms by SC injection to assess tolerability on the day before depot injections are commenced.

Initially, give 20 mg by IM injection every 4 weeks for 3 months, commencing on the day after the last SC injection. Adjust the dose according to response.

**Prevention of complications following pancreatic surgery:** 100 micrograms three times daily by SC injection for 7 consecutive days, starting on the day of the operation at least 1 hour before laparotomy.

**Variceal haemorrhage in patients with cirrhosis (unlicensed):** 25 micrograms/hour by continuous IV infusion for 48 hours. Doses up to 50 micrograms/hour have been used. Patients at high risk of re-bleeding may continue for up to 5 days.

**HIV-associated diarrhoea (unlicensed):** 100 micrograms three times daily by SC injection. If the diarrhoea is not controlled after a week the dose may be increased to 250 micrograms three times daily. Stop if not effective after a further week.

# Subcutaneous injection (preferred route)

#### Preparation and administration

- 1. Allow the injection to reach room temperature before administration.
- 2. Withdraw the required dose, taking care to select the smallest volume that will deliver the dose (this minimises the pain associated with SC injection).
- 3. Give by SC injection into the upper arm, thigh or abdomen. Injection-site rotation should be planned for subsequent injections to minimise discomfort.

# Intravenous injection (for use only when a rapid response is required)

#### Preparation and administration

- 1. Allow the injection to reach room temperature before administration.
- 2. Withdraw the required dose and dilute each mL to 2-10 mL with NaCl 0.9%.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over 3-5 minutes with ECG monitoring.

# Intramuscular injection (Sandostatin LAR depot injection only)

#### Preparation and administration

- 1. Allow the vial to reach room temperature before administration, but do not prepare until immediately before administration.
- 2. Lightly tap the vial to settle the powder at the bottom of the vial.
- 3. Attach one of the supplied needles to the solvent syringe and insert needle through the centre of the rubber stopper of the Sandostatin LAR vial.
- 4. Without disturbing the powder, gently inject the solvent into the vial by running it down the inside wall of the vial. Do not inject the solvent directly into the powder.
- 5. When complete, withdraw any excess air present in the vial.
- Do not disturb the vial until the solvent has wetted all the powder (usually takes about 2–5 minutes).
- 7. Swirl the vial moderately until a uniform suspension is formed. Do not shake vigorously.
- Inject 2 mL of air into the vial then, with the bevel down and the vial tipped at a 45° angle, slowly withdraw the entire contents of the vial into the syringe.
- 9. Change the needle (supplied) then gently invert the syringe to maintain a uniform suspension and eliminate air from syringe.
- 10. Give by IM injection into the gluteus muscle. Aspirate before injection to avoid inadvertent intravascular injection.

## Intravenous infusion (unlicensed)

- 1. Withdraw the required dose and add to 50-200 mL NaCl 0.9%.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion via volumetric infusion device or syringe pump over 15–30 minutes (or continuously depending upon indication) with ECG monitoring.

# Ofloxacin

#### 2 mg/mL solution in 100-mL infusion bottles

- Ofloxacin hydrochloride is a fluorinated quinolone antibacterial.
- It is used to treat infections caused by susceptible Gram-positive and Gram-negative bacteria.
- Ofloxacin is rapidly and well absorbed from the GI tract following oral dosing so the IV route should be used only when the oral route is unavailable.
- Doses are expressed in terms of the base: Ofloxacin 200 mg ≅ 220 mg ofloxacin hydrochloride.

# **Pre-treatment checks**

- · Do not give if there is known hypersensitivity to quinolone antibacterials.
- Avoid in patients with a past history of tendinitis, with a history of epilepsy or with a lowered seizure threshold, in pregnant or breast-feeding women.
- Use with caution if there is a history of psychiatric disease or in patients with latent or actual defects in G6PD activity.
- · Patients should be well hydrated and asked to drink fluids liberally.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure LFTs Renal function: U, Cr, CrCl (or eGFR)

## Dose

#### Complicated urinary tract infection: 200 mg daily.

Lower respiratory tract infection and septicaemia: 200 mg every 12 hours. In severe or complicated infections: the dose may be increased to 400 mg every 12 hours. Skin and soft-tissue infections: 400 mg every 12 hours.

Dose in renal impairment: adjusted according to creatinine clearance:1

- CrCl >20-50 mL/minute: 200-400 mg every 24 hours.
- CrCl 10-20 mL/minute: 200-400 mg every 24 hours.
- CrCl <10 mL/minute: 200 mg every 24 hours

**Dose in hepatic impairment:** in severe impairment or cirrhosis a maximum daily dose of 400 mg has been recommended.

## Intermittent intravenous infusion

- The infusion is pre-prepared for use. It should be clear and light yellow to amber. Inspect visually
  for particulate matter or discoloration prior to administration and discard if present.
- 2. Give by IV infusion over at least 30 minutes for 200 mg (at least 60 minutes for 400 mg).

SPC Tarivid IV infusion solution (accessed 2 April 2009).

# Olanzapine

#### 10-mg dry powder vials

This preparation must not be confused with the depot preparation.

- Olanzapine is a thienobenzodiazepine atypical antipsychotic. It has affinity for serotonin, muscarinic, histamine (H<sub>1</sub>), and adrenergic (alpha<sub>1</sub>, α<sub>1</sub>) receptors as well as various dopamine receptors.
- It is given IM for the rapid control of agitation and disturbed behaviours in patients with schizophrenia or mania, when oral therapy is not appropriate.

# **Pre-treatment checks**

- Do not give to patients with known risk of narrow-angle glaucoma.
- Do not give in cardiac illness: acute myocardial infarction, unstable angina, severe hypotension or bradycardia, sick sinus syndrome, recent heart surgery.
- If parenteral benzodiazepine treatment is also required, do not give until at least 1 hour after the IM olanzapine.
- Review the physical health of patient.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Blood pressure and pulse | Re |
|--------------------------|----|
| LFTs                     | Re |

Renal function: U, Cr, CrCl (or eGFR) Respiratory rate

## Dose

The maximum dose in 24 hours is 20 mg by all routes.

**Standard dose:** usually 5–10 mg (2.5–5 mg in elderly patients). An effect would be expected in 15–45 minutes. A second dose of 5–10 mg may be given after 2 hours if necessary. The number of injections should not exceed 3 daily for a maximum of 3 days.

Dose in renal impairment: consider a lower starting dose of 5 mg.

**Dose in liver impairment:** consider a lower starting dose of 5 mg in cirrhosis (Child–Pugh class A or B).

# 612 | Olanzapine

# Intramuscular injection

# Preparation and administration

- 1. Add 2.1 mL WFI to the vial and rotate until the contents have completely dissolved to give a clear yellow solution containing 5 mg/mL.
- 2. Withdraw the required dose.
- 3. Give by IM injection.

# Technical information

| Incompatible with           | Diazepam, haloperidol, lorazepam.                                                                                      |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------|
| Compatible with             | Solutions: WFI                                                                                                         |
| рН                          | Not relevant                                                                                                           |
| Sodium content              | Negligible                                                                                                             |
| Storage                     | Store below 25°C in original packaging.                                                                                |
| Displacement value          | Not relevant. The vial contains an overage so that the final solution contains 5 mg/mL when reconstituted as directed. |
| Stability after preparation | Reconstituted vials must be used within 1 hour.                                                                        |

# Monitoring

| Measure                             | Frequency                                                                | Rationale                                                                |
|-------------------------------------|--------------------------------------------------------------------------|--------------------------------------------------------------------------|
| Blood pressure                      | For at least 4 hours<br>after injection, e.g. at<br>15 minute intervals. | • May cause ↓BP.                                                         |
| Pulse                               |                                                                          | • May cause ↓pulse.                                                      |
| Respiratory rate                    |                                                                          | • May cause respiratory depression.                                      |
| Observe for signs of<br>EPSE or NMS | Throughout treatment                                                     | • May cause EPSE, e.g. muscles shakes and tremor,<br>or very rarely NMS. |

# Additional information

| Common and serious<br>undesirable effects | Infusion-related: Local: Injection-site discomfort.<br>Other: Drowsiness, respiratory depression, ↓BP, ↓pulse. May worsen symptoms<br>of Parkinson disease. |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pharmacokinetics                          | Elimination half-life is 32-50 hours. The effect of an IM dose could be expected in 15-45 minutes.                                                          |

(continued)

| Additional information (continued) |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |

# Olanzapine embonate (olanzapine pamoate)

210-mg, 300-mg and 405-mg dry powder vials with solvent (150 mg/mL after reconstitution)

This preparation is a depot preparation and must not be confused with olanzapine injection for rapid tranquillisation.

- Olanzapine embonate is a thienobenzodiazepine atypical antipsychotic. It has affinity for serotonin, muscarinic, histamine (H<sub>1</sub>), and adrenergic (alpha<sub>1</sub>, α<sub>1</sub>) receptors as well as various dopamine receptors.
- It is used for the maintenance treatment of adult patients with schizophrenia sufficiently stabilised during acute treatment with oral olanzapine.

# **Pre-treatment checks**

- Avoid in patients with Parkinson disease or with a known risk of narrow-angle glaucoma.
- Caution in patients with a low leucocyte and/or neutrophil count.
- Caution in patients on other medication known to ↑QTc interval, patients with congenital long QT syndrome, congestive heart failure, heart failure, heart hypertrophy, ↓K or ↓Mg.
- Caution in patients with a history of seizures as olanzapine may reduce the seizure threshold.
- Patients should be treated initially with oral olanzapine before administering prolonged-release injection to establish tolerability and response.
- Check that the patient will not travel alone to their destination after each injection.

## Dose

**Starting dose:** the patient should be treated with oral olanzapine initially to establish tolerability and response. The initial depot dose is dependent on the target oral olanzapine dose and is shown in Table O1.

Maintenance dose: after 2 months of treatment the recommended maintenance dose is as shown in Table O1.

| Table O1         Olanzapine depot maintenance dosing regimen |                                     |                                     |  |
|--------------------------------------------------------------|-------------------------------------|-------------------------------------|--|
| Target oral olanzapine<br>dose                               | Recommended starting<br>dose        | Maintenance after<br>2 months       |  |
| 10 mg/day                                                    | 210 mg/2 weeks or<br>405 mg/4 weeks | 150 mg/2 weeks or<br>300 mg/4 weeks |  |
| 15 mg/day                                                    | 300 mg/2 weeks                      | 210 mg/2 weeks or<br>405 mg/4 weeks |  |
| 20 mg/day                                                    | 300 mg/2 weeks                      | 300 mg/2 weeks                      |  |

**Dose in renal impairment:** a lower starting dose of 150 mg every 4 weeks should be considered. **Dose in hepatic impairment:** in moderate hepatic impairment (cirrhosis, Child–Pugh class A or B) start with 150 mg every 4 weeks and only increase with caution.

# Intramuscular injection

See Special handling below.

- 1. Loosen the powder by gently tapping the vial.
- Follow the manufacturer's detailed instructions included in the pack and withdraw the required volume of solvent. This is dependent on the strength of the vial being reconstituted, i.e. 1.3 mL (210 mg), 1.8 mL (300 mg) or 2.3 mL (405 mg). NB: There is more solvent in the vial than is needed for reconstitution.
- Continue to follow the instruction card carefully until a yellow, opaque suspension is formed containing 150 mg/mL.

- 4. Continue to follow the instruction card carefully to determine which of the needles supplied should be used to withdraw the dose, and which to administer the injection.
- 5. Give by deep IM injection into the gluteal muscle. Do not massage the injection site.

| Action in case of overdose                      | Treat symptomatically. Do <b>not</b> use adrenaline (epinephrine), dopamine or other sympathomimetic agents with beta-agonist activity since this may worsen JBP. Cardiovascular monitoring is necessary to detect possible arrhythmias.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Counselling                                     | Do not drive or operate machinery for the remainder of the day on which the injection is administered. Do not travel alone after receiving the injection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

# Omeprazole

#### 40-mg dry powder vials

- · Omeprazole sodium is a proton pump inhibitor (PPI).
- It is used IV when the oral route is temporarily unavailable, to treat conditions where inhibition of gastric acid secretion may be beneficial: treatment and prevention of gastric and duodenal ulcers, gastro-oesophageal reflux disease (GORD) and Zollinger–Ellison syndrome.
- It is also used (unlicensed) for acute GI bleeding and to prevent re-bleeding following therapeutic endoscopy for acute bleeding gastric or duodenal ulcers.
- There are two preparations available: IV injection and IV infusion. The IV injection preparation is accompanied by 10 mL special solvent containing macrogol 400, citric acid and WFI.
- Doses are expressed in terms of omeprazole:

Omeprazole  $40 \text{ mg} \equiv 42.6 \text{ mg}$  omeprazole sodium.

#### **Pre-treatment checks**

PPIs may mask symptoms of gastric cancer (and delay diagnosis); when a gastric ulcer is suspected the possibility of malignancy should be excluded before treatment is instituted.

#### Biochemical and other tests

LFTs

#### Dose

**Prophylaxis of acid aspiration:** 40 mg by IV injection or infusion completed 1 hour before surgery. **Benign gastric ulcer, duodenal ulcer and gastro-oesophageal reflux:** 40 mg by IV injection or infusion once daily, until oral administration is possible (recommended duration of treatment is up to 5 days).

Zollinger-Ellison syndrome: 60 mg by IV injection or infusion twice daily.

**Gastrointestinal haemorrhage following successful haemostasis of bleeding peptic ulcers** (unlicensed): 80 mg by IV injection followed by a continuous IV infusion of 8 mg/hour for 72 hours.<sup>1</sup> Dose in hepatic impairment: 20 mg daily by IV injection or infusion may be sufficient.

# Intermittent intravenous infusion (using the preparation for IV infusion)

#### Preparation and administration

- 1. Add approximately 5 mL NaCl 0.9% or Gluc 5% from a 100-mL bag to each omeprazole vial.
- 2. Mix thoroughly to dissolve and transfer the required dose to the infusion bag.
- 3. Repeat steps 1–2 to ensure the full dose is transferred or use a double-ended transfer needle device for the whole process.
- 4. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by IV infusion over 20–30 minutes.

# Intravenous injection

- 1. Withdraw 10 mL solvent from the ampoule and add approximately 5 mL to the omeprazole vial.
- 2. Immediately withdraw as much air as possible from the vial back into the syringe in order to reduce positive pressure and add the remaining solvent into the vial.
- 3. Rotate and shake the vial to ensure all the powder has dissolved.

## 618 | Omeprazole

- 4. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by IV injection over 5 minutes.

# Continuous intravenous infusion (using the preparation for IV infusion)

Various (unlicensed) regimens are used.

Preparation of a 200 mg/500mL solution (other strengths may be used)

- 1. Reconstitute each of 5 vials (total 200 mg) with 5 mL of NaCl 0.9% or Gluc 5% taken from a 500-mL infusion bag and mix thoroughly to dissolve.
- 2. Withdraw the required dose (ensuring the entire vial contents are transferred) and add to the 500-mL bag, e.g.  $5 \times 40$ -mg vials added to 500 mL NaCl 0.9% gives a solution containing 400 micrograms/mL. Mix well.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion at a rate of 8 mg/hour, i.e. 20 mL/hour of a 400 micrograms/mL solution. Prepare a fresh infusion bag every 24 hours.

# **Bibliography**

SPC Losec IV injection 40 mg, AstraZeneca UK (accessed 28 March 2010).

# Ondansetron

#### 2 mg/mL solution in 2-mL and 4-mL ampoules

- Ondansetron hydrochloride is a 5-HT<sub>3</sub> antagonist with antiemetic activity.
- It is used in the management of nausea and vomiting associated with cytotoxic chemotherapy and radiotherapy and in postoperative nausea and vomiting (PONV).
- Co-administration of dexamethasone may ↑efficacy of ondansetron.
- · Doses given by injection are expressed as ondansetron hydrochloride.

# **Pre-treatment checks**

- Caution with cardiac rhythm or conduction problems, check whether the patient is being treated with any antiarrhythmic, beta-blocker or any medication that may prolong the QT interval – IV ondansetron may cause transient ECG changes.
- Caution if there are any signs of subacute intestinal obstruction ondansetron can ↑large-bowel transit time.

#### Biochemical and other tests (not all are necessary in an emergency situation)

LFTs

#### Dose

**Chemotherapy and radiotherapy:** usually 8 mg by IM or IV injection immediately before treatment. Further doses are given by IM or IV injection, or by continuous IV infusion, depending on the emetogenic potential of the cytotoxic regimen.

Prevention of PONV: 4 mg by IM or IV injection at induction of anaesthesia.

Treatment of PONV: a single dose of 4 mg by IM or IV injection.

**Dose in hepatic impairment:** in moderate to severe hepatic impairment the total daily dose should not exceed 8 mg.

# Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

## Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over at least 30 seconds and preferably over 2-5 minutes.

# Intermittent intravenous infusion

- 1. Withdraw the required dose and add to 50-100 mL of NaCl 0.9% or Gluc 5%.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over at least 15 minutes.

# **Continuous intravenous infusion**

# Preparation and administration

- 1. Withdraw the required dose and add to a suitable volume of compatible infusion fluid. Mix well.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion for up to 24 hours.

# Additional information

| Common and serious<br>undesirable effects | Injection/infusion-related: Local: Injection-site reactions are common.<br>Other: Headache, constipation, sensation of warmth or flushing.                                                                                                                                                                                                                                                 |
|-------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pharmacokinetics                          | Elimination half-life is approximately 3 hours.                                                                                                                                                                                                                                                                                                                                            |
| Significant interactions                  | <ul> <li>The following may ↓ondansetron levels or effect:<br/>carbamazepine, phenytoin, rifampicin.</li> <li>Ondansetron may ↑levels or effect (or ↑side-effects) of QT-prolonging<br/>drugs (may result in additional QT prolongation).</li> <li>Ondansetron may ↓levels or effect of tramadol (higher doses of tramadol<br/>required, which also increase its emetogenicity).</li> </ul> |
| Action in case of overdose                | Stop administration and give supportive therapy as appropriate.                                                                                                                                                                                                                                                                                                                            |

## 622 | Ondansetron | Oxycodone hydrochloride

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Zofran Injection, Flexi-Amp injection (accessed 21 January 2010).

- SPC Ondansetron 2 mg/mL injection, Hospira UK (accessed 21 January 2010).
- SPC Ondansetron 2 mg/mL solution for injection, Wockhardt UK Ltd (accessed 21 January 2010).

# **Oxycodone hydrochloride**

#### 10 mg/mL solution in 1-mL and 2-mL ampoules

#### 50 mg/mL solution in 1-mL ampoules

- Oxycodone hydrochloride is a potent opioid analgesic. It is roughly twice as potent as morphine for a given dose and route.
- It is used parenterally for the treatment of moderate to severe pain, particularly in palliative care.

# **Pre-treatment checks**

- Do not use in acute respiratory depression, where there is a risk of paralytic ileus, in ↑intracranial
  pressure and in head injury, in comatose patients; in acute abdomen; delayed gastric emptying;
  chronic constipation; cor pulmonale; acute porphyria.
- Caution in JBP, shock, convulsive disorders, supraventricular tachycardias, atrial flutter, chronic
  obstructive pulmonary disease and acute asthma attack, obstructive or inflammatory bowel diseases, biliary tract diseases, alcoholism, prostatic hyperplasia, myasthenia gravis, hypothyroidism
  (reduce dose), adrenocortical insufficiency (reduce dose).
- · Caution in toxic psychosis and pancreatitis.
- · Ensure resuscitation equipment and naloxone are available especially for IV administration.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure and pulse Bodyweight (certain indications) LFTs Pain score Renal function: U, Cr, CrCl (or eGFR) Respiratory rate

## Dose

Note: Doses above those stated must not be given to opioid-naive patients.

**Moderate to severe pain:** initially 1–10 mg by IV injection or 5 mg by SC injection every 4 hours when required. Halve the dose in elderly or frail patients. The initial dose is dependent on previous opioid exposure – see below.

#### Approximate equivalents for patients switched from oral to parenteral dosing

5 mg orally every 4 hours (or 30 mg daily as oral modified release) is equivalent to

- 2.5 mg by SC injection every 4 hours (total 15 mg daily)
- 2.5 mg by IV injection every 4 hours (total 15 mg daily)
- 15 mg by IV or SC infusion over 24 hours

Alternatively, give 2 mg/hour by IV infusion and adjust dose according to requirements. **Patient-controlled analgesia:** the usual setting for the PCA device is to deliver a 0.03 mg/kg bolus with a minimum 5-minute lock-out period.

**Dose in renal impairment:** reduce the dose if creatinine clearance < 10 mL/minute. **Dose in hepatic impairment:** reduce dose or avoid (may precipitate coma).

# **Subcutaneous injection**

Preparation and administration

Check that you have selected the correct strength of ampoule. High-strength ampoules are available for use in PCA and palliative care. These are not suitable for use in acute situations.

- 1. Withdraw the required dose.
- 2. Give by SC injection.
- Close monitoring of respiratory rate and consciousness recommended for 30 minutes in patients receiving initial dose, especially elderly patients or those of low bodyweight.

## Intravenous injection

#### Preparation and administration

Check that you have selected the correct strength of ampoule. High-strength ampoules are available for use in PCA and palliative care. These are not suitable for use in acute situations.

- 1. Withdraw the required dose and dilute with NaCl 0.9% or Gluc 5% to give a solution containing 1 mg/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV injection over a minimum of 2 minutes.
- Close monitoring of respiratory rate and consciousness recommended for 30 minutes in patients receiving initial dose, especially elderly patients or those of low bodyweight.

### Intravenous infusion

- 1. Withdraw the required dose and add to a suitable volume of NaCl 0.9% or Gluc 5% to give a solution containing 1 mg/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion at the desired rate via a volumetric infusion device or syringe pump. Adjust the dose to clinical response.

# Patient-controlled analgesia<sup>1</sup>

Preparation and administration

Strength used may vary depending on local policies.

- 1. Make 50 mg oxycodone up to 50 mL with NaCl 0.9% or Gluc 5% in a PCA syringe to give a solution containing 1 mg/mL.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. The usual setting for the PCA device is to deliver a 0.03 mg/kg bolus with a minimum 5-minute lock-out period. Lower doses are used in patients with severe renal impairment.

# Pabrinex Intramuscular High Potency Injection

## No. 1 (5-mL) and No. 2 (2-mL) ampoules

Each No. 1 ampoule (5 mL) contains:

#### Thiamine 250 mg, riboflavin (as phosphate sodium) 4 mg, pyridoxine 50 mg

Each No. 2 ampoule (2 mL) contains:

#### Ascorbic acid 500 mg, nicotinamide BP 160 mg

- Pabrinex ampoules are given in pairs and each pair of Pabrinex ampoules provides high potency B
  complex vitamins and vitamin C.
- Pabrinex is used to reverse severe depletion or malabsorption of these vitamins, particularly in alcoholism, after acute infections, postoperatively and in psychiatric states.

#### MHRA/CHM advice (September 2007)

Although potentially serious allergic adverse reactions may rarely occur during, or shortly after, parenteral administration, the CHM has recommended that:

- This should not preclude the use of parenteral thiamine in patients where this route of administration is required, particularly in patients at risk of Wernicke-Korsakoff syndrome where treatment with thiamine is essential.
- Facilities for treating anaphylaxis (including resuscitation facilities) should be available when parenteral thiamine is administered.

## **Pre-treatment checks**

- Repeated injections may give rise to anaphylactic shock. Mild allergic reactions such as sneezing or mild asthma are warning signs that further injections may give rise to anaphylactic shock.
- In thiamine deficiency \carbohydrate load including the use of high-strength parenteral glucose solutions may \thiamine requirements and worsen symptoms.

#### Dose

Pabrinex injection is also available in an IV form which **must not** be given IM. Ensure the correct preparation has been selected before administration.

The contents of ampoules No. 1 and No. 2 (total 7 mL) combine to form the dose. **Standard dose:** 7 mL twice daily for up to 7 days.

## Intramuscular injection

- 1. Make up the total dose by mixing the contents of ampoules Nos. 1 and 2 in a syringe (total 7 mL).
- Give by slow IM injection high into the gluteal muscle, 5 cm below the iliac crest. Rotate injection sites for subsequent injections.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Pabrinex IM HP (accessed 21 October 2008). SPC Ascorbic Acid Injection BPC UCB Pharma (accessed 20 October 2008).

# Pabrinex Intravenous High Potency Injection

#### No. 1 and No. 2 ampoules each containing 5 mL

Each No. 1 ampoule contains per 5 mL:

#### **Thiamine 250 mg, riboflavin (as phosphate sodium) 4 mg, pyridoxine 50 mg** *Each No. 2 ampoule contains per 5 mL:*

#### Ascorbic acid 500 mg, nicotinamide BP 160 mg, anhydrous glucose BP 1g

- Pabrinex ampoules are given in pairs and each pair of Pabrinex ampoules provides high potency B
  complex vitamins and vitamin C.
- Pabrinex is used to reverse severe depletion or malabsorption of these vitamins, particularly in
  alcoholism, after acute infections, postoperatively, in psychiatric states and in prevention of
  refeeding syndrome.
- The IV form is also used to maintain levels of vitamins B and C in patients on chronic intermittent haemodialysis.

#### MHRA/CHM advice (September 2007)

Although potentially serious allergic adverse reactions may rarely occur during, or shortly after, parenteral administration, the CHM has recommended that:

- This should not preclude the use of parenteral thiamine in patients where this route of administration is required, particularly in patients at risk of Wernicke–Korsakoff syndrome where treatment with thiamine is essential.
- IV administration should be by infusion over 30 minutes.
- Facilities for treating anaphylaxis (including resuscitation facilities) should be available when parenteral thiamine is administered.

## **Pre-treatment checks**

 Repeated injections may give rise to anaphylactic shock. Mild allergic reactions such as sneezing or mild asthma are warning signs that further injections may give rise to anaphylactic shock.  In thiamine deficiency \carbohydrate load including the use of high-strength parenteral glucose solutions may \thiamine requirements and worsen symptoms.

#### Dose

Pabrinex injection is also available in an IM form which **must not** be given IV. Ensure the correct preparation has been selected before administration.

Equal volumes of the contents of ampoules No. 1 and No. 2 combine to form the dose.

**Coma or delirium from alcohol, narcotics or barbiturates; collapse following continuous narcosis:** give 20–30 mL of the mixed ampoules by IV infusion every 8 hours.

**Psychosis following narcosis or ECT; toxicity from acute infections:** give 10 mL of the mixed ampoules by IV infusion twice daily for up to 7 days.

**Haemodialysis:** give 10 mL of the mixed ampoules by IV infusion every 2 weeks at the completion of dialysis.

**Prevention of refeeding syndrome in susceptible individuals (unlicensed):** 10 mL of the mixed ampoules has been given by IV infusion twice daily for 10 days.

# Intravenous infusion

#### Preparation and administration

- 1. Make up the total dose by mixing equal volumes of ampoules Nos. 1 and 2 in a syringe.
- 2. Add to 100 mL of NaCl 0.9% or Gluc 5%.
- 3. Give by IV infusion over 30 minutes.

# Palifermin

### 6.25-mg dry powder vials

- Palifermin is a human keratinocyte growth factor (KGF) produced by recombinant DNA technology in *Escherichia coli*.
- It is used to reduce the incidence and duration of severe oral mucositis in patients with haematological neoplasms undergoing myeloablative chemotherapy, before stem cell transplantation.

### **Pre-treatment checks**

Do not use if there is known hypersensitivity to palifermin or any *E. coli*-derived proteins and avoid in breast feeding.

Biochemical and other tests

Bodyweight

### Dose

In all cases be guided by the oncology team responsible for treating the patient.

**Standard dose:** 60 micrograms/kg daily on three consecutive days (*doses 1 to 3*) before and three consecutive days after myeloablative chemotherapy (doses 4 to 6).

*Doses 1 to 3* are given on the three consecutive days prior to myeloablative chemotherapy, with the third dose administered 24–48 hours before chemotherapy.

*Doses 4 to 6* are given on the three consecutive days after myeloablative chemotherapy with the first of these (dose 4) administered after, but on the same day as, stem cell infusion and at least 4 days after dose 3.

### Intravenous injection

- 1. Slowly inject 1.2 mL WFI into the vial.
- Swirl the contents gently to dissolve (usually takes less than 5 minutes) but do not shake vigorously. This produces a solution containing 5 mg/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Withdraw the required dose.
- Give by IV injection. If heparin is being used to maintain the IV line, NaCl 0.9% should be used to flush the line prior to and after administration of palifermin. Palifermin should **not** be filtered during preparation or administration.

| Sodium content                    | Nil                                                                                                                                                                                           |  |
| Storage                           | Store at 2-8°C in original packaging. Do not freeze.                                                                                                                                          |  |
| Displacement value                | Negligible                                                                                                                                                                                    |  |
| Stability after<br>preparation    | From a microbiological point of view, should be used immediately; however, reconstituted vials may be stored at 2-8°C for 24 hours (only stable for a maximum of 1 hour at room temperature). |  |

# Monitoring

Nothing specific. Palifermin can sometimes cause *ilipase* and amylase levels with or without symptoms of abdominal pain or backache thought to be salivary in origin and non-serious.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# **Bibliography**

SPC Kepivance 6.25 mg powder for solution for injection (accessed 2 April 2009).

# **Palonosetron**

### 50 micrograms/mL solution 5-mL ampoules

- Palonosetron hydrochloride is a 5-HT<sub>3</sub> antagonist with antiemetic activity.
- It is used in the prevention of nausea and vomiting associated with moderate and highly emetogenic cytotoxic chemotherapy.
- Co-administration of a corticosteroid may ↑efficacy of palonosetron.
- Doses are expressed in terms of the base: Palonosetron 250 micrograms ≅ 281 micrograms palonosetron hydrochloride.

### **Pre-treatment checks**

- Caution in patients receiving drugs that may \u03c6QT interval or patients who have or may develop
  prolongation of the QT interval.
- Caution in history of constipation or intestinal obstruction may ↑large bowel transit time.

### Biochemical and other tests

Electrolytes: serum K

### Dose

**Standard dose**: 250 micrograms by IV injection 30 minutes before the start of chemotherapy. Do not repeat the dose within 7 days.

## Intravenous injection

- 1. Withdraw the required dose.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 30 seconds.

# Bibliography

SPC Aloxi (accessed 29 December 2009).

# Pamidronate disodium (disodium pamidronate)

### 15-mg, 30-mg, 90-mg dry powder vials with either 5 mL or 10 mL solvent (Aredia) 15 mg/mL solution in 1-mL, 2-mL, 4-mL and 6-mL ampoules 3 mg/mL solution in 5-mL, 10-mL, 20-mL and 30-mL vials

- Pamidronate disodium is an aminobisphosphonate with properties similar to other bisphosphonates. It inhibits bone resorption, but appears to have less effect on bone mineralisation.
- It is used to treat conditions characterised by increased osteoclast activity: tumour-induced \Ca; osteolytic lesions and bone pain in patients with bone metastases associated with breast cancer or multiple myeloma; Paget disease (of bone).
- Not all products are licensed for all indications; individual products vary in their specifications for suitable dilutions and rates of administration.
- Doses are expressed as pamidronate disodium.

### **Pre-treatment checks**

- Do not give to patients already receiving other bisphosphonates.
- Do not give in renal impairment when CrCl (or eGFR) < 30 mL/minute unless life-threatening tumour-induced  $\uparrow$ Ca where the benefit outweighs risk.

- Osteonecrosis of the jaw can occur: consider dental examination and preventive dentistry prior to *planned* treatment in patients with risk factors (e.g. cancer, chemotherapy, radiotherapy, corticosteroids, poor oral hygiene). Avoid invasive dental procedures during treatment if possible.
- Give cautiously to patients who have had previous thyroid surgery (increased risk of ↓Ca).
- Contraindicated in pregnancy. Women of child-bearing potential should take contraceptive precautions during *planned* treatment.
- Unless being used for ↑Ca, prescribe oral calcium and vitamin D supplements in those at risk of deficiency (e.g. through malabsorption or lack of exposure to sunlight) and in patients with Paget disease to minimise ↓Ca.
- Hydrate the patient adequately before, during and after infusions. Calcium level may return to normal simply by rehydration of the patient. Recheck Ca before commencing infusion.

### Biochemical and other tests

Electrolytes: serum Na, K, Ca, PO<sub>4</sub>, Mg Renal function: U, Cr, CrCl (or eGFR)

### Dose

**Tumour-induced hypercalcaemia (TIH):** the total dose is dependent on initial serum Ca (see Table P1 below – dose ranges are valid for both 'uncorrected' and 'corrected' Ca). Give the total dose either as a single infusion or as multiple smaller infusions over 2–4 consecutive days, with a maximum dose per treatment course of 90 mg.

| Table P1         Pamidronate dosing regimen in TIH                          |           |       |  |  |
|-----------------------------------------------------------------------------|-----------|-------|--|--|
| Initial serum calcium ('corrected' or 'uncorrected') Recommended total dose |           |       |  |  |
| mmol/L                                                                      | mg/dL     | (mg)  |  |  |
| <3.0                                                                        | <12.0     | 15-30 |  |  |
| 3.0-3.5                                                                     | 12.0-14.0 | 30-60 |  |  |
| 3.5-4.0                                                                     | 14.0-16.0 | 60-90 |  |  |
| >4.0                                                                        | >16.0     | 90    |  |  |

**Dose in renal impairment for TIH:** adjusted according to creatinine clearance:<sup>1</sup>

- CrCl ≥10 mL/minute: dose as in normal renal function.
- CrCl <10 mL/minute: Ca >4.0 mg/dL, dose at 60 mg; Ca <4.0 mg/dL, dose at 30 mg.

# **Osteolytic lesions and bone pain in multiple myeloma:** 90 mg every 4 weeks. **Osteolytic lesions and bone pain in bone metastases associated with breast cancer:** 90 mg

every 4 weeks (or may also be given 3-weekly to coincide with chemotherapy).

Paget disease of bone: give the course either as:

- 30 mg weekly for 6 consecutive weeks (total dose 180 mg).
- An initial dose of 30 mg (to minimise first-dose side-effects), followed by three doses of 60 mg every other week (total dose of 210 mg).

Increase the dose according to disease severity, to a maximum total dose of 360 mg (in divided doses of 60 mg). Repeat the course every 6 months until disease remission, or if relapse occurs.

### Intermittent intravenous infusion

- Pamidronate disodium is incompatible with Hartmann's and Ringer's (contain Ca).
- The patient must be adequately hydrated using NaCl 0.9% before dosing for *†*Ca.
- Infusion into a relatively large vein minimises patient discomfort.

- 1. For dry powder vials: reconstitute with the solvent supplied. Dissolve vial contents completely before withdrawing the dose. Concentration is 15 mg/5 mL, 30 mg/10 mL or 90 mg/10 mL depending on vial size.
- 2. For all presentations: withdraw the required dose.
- Add each dose of 30 mg to a minimum of 100 mL NaCl 0.9%; add each dose of 60–90 mg to a minimum of 250 mL NaCl 0.9%.
- 4. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by IV infusion into a relatively large vein (to minimise local reactions) at a maximum rate of 60 mg/hour (1 mg/minute). In impaired renal function give at a maximum rate of 20 mg/hour.

# **Pantoprazole**

### 40-mg dry powder vials

- · Pantoprazole sodium is a proton pump inhibitor (PPI).
- It may be used IV when the oral route is temporarily unavailable, to treat conditions where inhibition of gastric acid secretion may be beneficial: treatment and prevention of gastric and duodenal ulcers, gastro-oesophageal reflux disease (GORD) and Zollinger–Ellison syndrome.
- Doses are expressed in terms of pantoprazole: Pantoprazole 40 mg ≈ 45.1 mg pantoprazole sodium.

### **Pre-treatment checks**

- Zinc supplementation should be considered during IV therapy in patients prone to zinc deficiency

   the preparation contains edetate disodium, which is a potent metal ion chelator.
- · Caution also when used concomitantly with other IV preparations containing edetate disodium.

### **Biochemical tests**

LFTs

### Dose

### Duodenal ulcer, gastric ulcer, and gastro-oesophageal reflux: 40 mg daily.

**Zollinger–Ellison syndrome (and other hypersecretory conditions):** initially 80 mg (160 mg if rapid acid control is required) then 80 mg once daily, adjusted according to response; give daily doses above 80 mg in two divided doses.

Dose in hepatic impairment: in severe impairment, the daily dose should be reduced to 20 mg.

### Intravenous injection

### Preparation and administration

- 1. Reconstitute each 40-mg vial with 10 mL NaCl 0.9% to make a 4 mg/mL solution.
- 2. Withdraw the required dose.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration. Discard if present.
- 4. Give by IV injection over 2 minutes.

### Intravenous infusion

- 1. Reconstitute each 40-mg vial with 10 mL NaCl 0.9% to make a 4 mg/mL solution.
- Withdraw the required dose and add to 100 mL of compatible infusion fluid (NaCl 0.9% or Gluc 5%).
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration. Discard if present.
- 4. Give by IV infusion over 15 minutes.

SPC Protium i.v. powder for solution for injection (accessed 26 June 2009).

# **Papaveretum**

### 15.4 mg/mL solution in 1-mL ampoules

This preparation must not be confused with papaverine.

- Papaveretum is a mixture of opium alkaloids and in the UK contains the hydrochlorides of morphine, codeine, and papaverine. In the past it additionally contained noscapine but this was removed from the UK formulation in 1993; it may still be contained in this product in other countries.
- It is licensed for premedication, enhancement of anaesthesia, postoperative analgesia and for severe chronic pain.
- Doses are expressed as papaveretum: Papaveretum 15.4 mg ≅ 10 mg anhydrous morphine.

### **Pre-treatment checks**

- Do not use in acute respiratory depression, where there is a risk of paralytic ileus, in ↑intracranial
  pressure and in head injury, in comatose patients, in heart failure secondary to chronic lung
  disease and phaeochromocytoma.
- Caution in JBP, shock, convulsive disorders, supraventricular tachycardias, atrial flutter, chronic
  obstructive pulmonary disease and acute asthma attack, obstructive or inflammatory bowel diseases, biliary tract diseases, alcoholism, prostatic hyperplasia, myasthenia gravis, hypothyroidism
  (reduce dose), adrenocortical insufficiency (reduce dose).
- · Caution in elderly patients or those of low bodyweight.
- · Ensure that resuscitation equipment and naloxone are available, especially for IV administration.

### Biochemical and other tests (not all are necessary in an emergency situation)

| Blood pressure and pulse | Renal function: U, Cr, CrCl (or eGFR) |
|--------------------------|---------------------------------------|
| LFTs                     | Respiratory rate                      |
| Pain score               |                                       |

### Dose

The CSM has advised (in 1993) that to avoid confusion the figures 7.7 mg or 15.4 mg should be used for prescribing purposes.

**Standard dose:** 7.7–15.4 mg by IM or SC injection every 4 hours if necessary (elderly patients initially 7.7 mg) If given by IV injection the dose should be reduced to 25–50% of the corresponding IM or SC dose. **Pre-operative medication:** 7.7–15.4 mg by IM or SC injection.

**Dose in renal impairment:** reduce the dose or avoid (especially if severe). **Dose in hepatic impairment:** reduce the dose or avoid.

### Intramuscular injection (preferred route)

- 1. Withdraw the required dose.
- 2. Give by IM injection.
- 3. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

# **Subcutaneous injection**

### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by SC injection.
- 3. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

### **Intravenous injection**

-l :-

### Preparation and administration

- 1. Withdraw the required dose. It may be diluted to 10 mL with NaCl 0.9% or Gluc 5% to facilitate slow administration.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV injection over 2-3 minutes.
- 4. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Martindale Pharmaceuticals Papaveretum Injection BP 15.4 mg/mL (received 26 February 2009).

# Papaveretum with hyoscine hydrobromide

Solution in 1-mL ampoules (= papaveretum 15.4 mg/mL with hyoscine hydrobromide 400 micrograms/mL)

This preparation must not be confused with papaverine.

- Papaveretum is a mixture of opium alkaloids and in the UK contains the hydrochlorides of morphine, codeine, and papaverine. In the past it additionally contained noscapine but this was removed from the UK formulation in 1993; it may still be contained in this product in other countries.
- Hyoscine hydrobromide is a tertiary amine with antimuscarinic activity which reduces secretions during surgery.
- The preparation is licensed for premedication.
- Papaveretum 15.4 mg ≈ 10 mg anhydrous morphine.
- · Doses below are quoted in millilitres of the combined product.

### **Pre-treatment checks**

- Do not use in acute respiratory depression, where there is a risk of paralytic ileus, in ↑intracranial
  pressure and in head injury, in comatose patients, in heart failure secondary to chronic lung
  disease and phaeochromocytoma.
- Caution in JBP, shock, convulsive disorders, supraventricular tachycardias, atrial flutter, chronic
  obstructive pulmonary disease and acute asthma attack, obstructive or inflammatory bowel diseases, biliary tract diseases, alcoholism, prostatic hyperplasia, myasthenia gravis, hypothyroidism
  (reduce dose), adrenocortical insufficiency (reduce dose).
- · Caution in elderly patients or those of low bodyweight.
- Ensure that resuscitation equipment and naloxone are available, especially for IV administration.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Blood pressure and pulse | Renal function: U, Cr, CrCl (or eGFR) |
|--------------------------|---------------------------------------|
| LFTs                     | Respiratory rate                      |

### Dose

**Preoperative medication:** 0.5–1 mL as a single dose by IM or SC injection 45–60 minutes before anaesthesia (use 0.5 mL in elderly patients or those of low bodyweight and frail). **Dose in renal impairment:** avoid if CrCl <20 mL/minute.

Dose in hepatic impairment: reduce dose or avoid (may precipitate coma).

### Intramuscular injection (preferred route)

- 1. Withdraw the required dose.
- 2. Give by IM injection.
- Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

### **Subcutaneous injection**

### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by SC injection.
- 3. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# **Bibliography**

SPC Martindale Pharmaceuticals, Papaveretum and hyoscine injection 15.4 mg and 400 micrograms/ mL (received 26 February 2009).

# Paracetamol (acetaminophen)

### 10 mg/mL solution in 50-mL and 100-mL vials

- Paracetamol has analgesic and antipyretic activity and some anti-inflammatory activity.
- It is used IV for the short-term treatment of moderate pain and pyrexia when administration by other routes is not possible or appropriate.
- It provides onset of pain relief within 5–10 minutes and exerts its antipyretic effect within 30 minutes.

### Pre-treatment checks

- · Avoid in severe hepatic impairment.
- · Caution in non-severe hepatic impairment, renal impairment, alcoholism, chronic malnutrition due to low hepatic glutathione reserves and dehydration.

### Biochemical and other tests

LFTs Renal function: U, Cr, CrCl (or eGFR)

### Dose

**Adult**  $\geq$ **50 kg:** 1 g every 4–6 hours when required. Maximum 4 g in any 24-hour period.

**Adult** <**50 kg:** 15 mg/kg (1.5 mL/kg) every 4–6 hours when required. Maximum 60 mg/kg daily (without exceeding 3 g in any 24-hour period).

Dose in renal impairment: adjusted according to CrCl:

• CrCl < 30 mL/minute: normal adult dose but increase dose interval to a minimum of 6 hours.

**Dose in hepatic impairment:** in adults with hepatocellular insufficiency, chronic alcoholism, chronic malnutrition (low reserves of hepatic glutathione) or dehydration, the maximum daily dose must not exceed 3 g.

### Intermittent intravenous infusion

- 1. Select the appropriate dose.
- 2. The infusion is pre-prepared for use. It should be clear and slightly yellowish. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 15 minutes.

### Bibliography

SPC Perfalgan 10 mg/mL solution for infusion (accessed 25 January 2010).

# Parathyroid hormone (human recombinant parathyroid hormone)

### 1.61 mg powder plus solvent in dual-chamber cartridge for use in Preotact pen

- Parathyroid hormone (PTH) is secreted by the parathyroid gland and maintains normal concentrations of ionised Ca in extracellular fluid. It increases renal reabsorption of Ca and decreases PO<sub>4</sub> excretion. It also promotes the conversion of vitamin D to its active metabolite, which increases Ca absorption from the GI tract.
- PTH acts on bone to accelerate the release of Ca and PO<sub>4</sub> into the extracellular fluid: LCa stimulates PTH secretion, whereas ↑Ca has an inhibitory effect. 1,25-Dihydroxycholecalciferol can also suppress PTH secretion.
- Therapeutically, PTH is used for the treatment of osteoporosis in postmenopausal women at high risk of fractures.

### **Pre-treatment checks**

- PTH is for use in postmenopausal women, there is no data available for other patient groups.
- Do not use in hypercalcaemia, other disturbances of calcium-phosphate metabolism or if bonespecific Alk Phos is raised.
- Do not use in patients with metabolic bone disease such as hyperparathyroidism and Paget disease.
- Do not use in patients who have received radiation therapy to the skeleton.
- May be used in mild to moderate hepatic impairment (Child-Pugh 7–9). Do not use in severe hepatic impairment.
- Prescribe oral calcium and vitamin D supplements if dietary intake is inadequate.

### Biochemical and other tests

Electrolytes: serum Ca, PO<sub>4</sub>, Mg LFTs Renal function: U, Cr, CrCl (or eGFR)

### Dose

**Standard dose:** 100 micrograms once daily by SC injection for up to 24 months. Each dual-chamber cartridge provides 14 doses of 100 micrograms. All patients should receive

training in the use of the pen and a user manual is provided with each pen.

Dose in renal impairment: do not give if CrCl < 30 mL/minute.

### **Subcutaneous injection**

- 1. Refer to the Preotact user manual for full details of reconstitution and administration.
- The solution should be clear and colourless. Inspect visually and discard cartridge if solution is cloudy, coloured or contains particles.
- 3. Give the dose by SC injection, taking care to rotate injection sites.

# Parecoxib

### 20-mg and 40-mg dry powder vials with solvent (NaCl 0.9%)

- Parecoxib sodium is a selective COX-2 inhibitor.
- · It is used for the short-term management of acute postoperative pain.
- Doses are expressed in terms of the base:
   Parecoxib 40 mg = 42.4 mg parecoxib sodium.

### **Pre-treatment checks**

Avoid in patients with a history of severe allergic drug reactions to aspirin or NSAIDs (including COX-2 inhibitors), active peptic ulceration or GI bleeding, inflammatory bowel disease, congestive heart failure, post coronary artery bypass graft, severe hepatic failure (Child–Pugh score >10 or serum albumin <25 g/L).

### Biochemical and other tests

| Blood pressure            | LFTs                                  |
|---------------------------|---------------------------------------|
| Electrolytes: serum Na, K | Renal function: U, Cr, CrCl (or eGFR) |

### Dose

**Postoperative pain:** 40 mg by IV or IM injection, then 20–40 mg every 6–12 hours as required. Maximum daily dose is 80 mg. There is limited experience of treating for more than 3 days.

Dose in renal impairment: adjusted according to creatinine clearance:<sup>1</sup>

- CrCl >30-50 mL/minute: dose as in normal renal function; use with caution.
- CrCl 10-30 mL/minute: dose as in normal renal function; avoid if possible.
- CrCl <10 mL/minute: dose as in normal renal function but avoid unless on dialysis.

### Intravenous injection

### Preparation and administration

- 1. Reconstitute each 20-mg vial with 1 mL solvent (use 2 mL for each 40-mg vial).
- 2. Gently swirl the vial to dissolve the powder to give a solution containing 20 mg/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Withdraw the required dose.
- 5. Give by rapid IV injection.

### Intramuscular injection

- 1. Reconstitute each 20-mg vial with 1 mL solvent (use 2 mL for each 40-mg vial).
- 2. Gently swirl the vial to dissolve the powder to give a solution containing 20 mg/mL.
- 3. Withdraw the required dose.
- 4. Give by deep IM injection

# 652 | Parecoxib

# **Paricalcitol**

### 5 micrograms/mL solution in 1-mL and 2-mL ampoules

monograph. These may not all be applicable in some clinical situations.

- Paricalcitol is an analogue of calcitriol, the active form of vitamin D. It is reported to have less
  effect on Ca and PO<sub>4</sub> concentrations while retaining the suppressive effect on parathyroid
  hormone (PTH).
- It is indicated for the prevention and treatment of secondary hyperparathyroidism in patients with chronic renal failure undergoing haemodialysis. Paricalcitol may also be given orally for this indication.

### **Pre-treatment checks**

Do not give to patients with hypercalcaemia, including hypercalcaemia of malignancy.

### Biochemical and other tests

Baseline PTH level (measured in either picomol/L or pg/mL) Electrolytes: serum Ca (corrected), PO<sub>4</sub> Liver function: Alk Phos Renal function: U, Cr, CrCl (or eGFR)

### Dose

Initial dose: calculated using baseline intact PTH levels (formula depends on reported PTH units):

 $Initial dose (micrograms) = \frac{Baseline intact PTH level (picomol/L)}{8}$  $Initial dose (micrograms) = \frac{Baseline intact PTH level (picograms/mL)}{80}$ 

Give the dose no more frequently than every other day at any time during dialysis. The maximum dose used in clinical studies was as high as 40 micrograms.

### 654 | Paricalcitol

### Titration dose

- The currently accepted target range for PTH levels in end-stage renal failure subjects undergoing dialysis is no more than 1.5–3 times the non-uremic ULN, i.e. 15.9–31.8 picomol/L (150–300 picograms/mL) for intact PTH.
- Close monitoring and individual dose titration are necessary to adjust treatment.
- If the patient is hypercalcaemic or (corrected Ca × PTH level) > 5.2 mmol<sup>2</sup>/L<sup>2</sup> (65 mg<sup>2</sup>/dL<sup>2</sup>), reduce the dose or stop treatment until these parameters have returned to normal values.
- At this point, paricalcitol may be restarted at a lower dose.
- The dose may need to be decreased as the PTH levels reduce in response to therapy.
- Table P2 gives further guidance on how to adjust the dose.

 Table P2
 Suggested paricalcitol dosing guidelines (dose adjustments at 2-4 week intervals)

| Intact PTH level relative to baseline         | Paricalcitol dose adjustment |
|-----------------------------------------------|------------------------------|
| Same or increased                             | Increase by 2-4 micrograms   |
| Decreased by <30%                             |                              |
| Decreased by 30-60%                           | Continue with current dose   |
| Decreased >60%                                | Decrease by 2-4 micrograms   |
| Intact PTH <15.9 picomol/L (150 picograms/mL) |                              |

### Via haemodialysis access

### Preparation and administration

- 1. Withdraw the required dose.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration.
- 3. Give by IV injection via haemodialysis access before, during or after haemodialysis sessions.

| Technical inform  | Technical information                                                                                                                                                              |  |  |  |  |  |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Zemplar 5 microgram/ml solution for injection (accessed 25 January 2009).

# Pegfilgrastim

### $10\,mg/mL$ (expressed as filgrastim) solution in pre-filled syringe: $6\,mg/0.6\,mL$

- Pegfilgrastim is pegylated recombinant methionyl human granulocyte colony-stimulating factor (G-CSF), produced using r-DNA technology in *E. coli*. It acts primarily on neutrophil precursors to increase neutrophil levels and has a more sustained action than filgrastim.
- It is used to treat or prevent neutropenia in patients receiving myelosuppressive cancer chemotherapy (except in chronic myeloid leukaemia and myelodysplastic syndromes),
- Doses are expressed as milligrams of filgrastim.

# Pre-treatment checks

- Contraindicated in chronic myeloid leukaemia, secondary acute myeloid leukaemia, and myelodysplastic syndromes.
- Caution recommended in acute myeloid leukaemia.
- Check recent pulmonary history (recent history of pulmonary infiltrates or pneumonia *\(\pi\)*risk of pulmonary adverse events).
- Confirm whether women of child-bearing potential are pregnant or breast feeding (contraindicated unless benefit outweighs risk, at discretion of clinician).
- Ensure patient is adequately hydrated.
- Ensure patient not allergic to latex (needle sheath of the pre-filled syringe contains natural dry rubber).

# Biochemical and other tests

FBC

# Dose

**Standard dose:** 6 mg given by SC injection for each chemotherapy cycle starting approximately 24 hours after cytotoxic chemotherapy.

# Subcutaneous injection

- 1. The pre-filled syringe should not be shaken as this may inactivate pegfilgrastim.
- 2. Give by SC injection.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# **Bibliography**

SPC Neulasta, Amgen (accessed 5 June 2009).

# Pegvisomant

### 10-mg, 15-mg, 20-mg dry powder vials plus solvent

- Pegvisomant is a genetically modified analogue of human growth hormone and is a highly selective growth hormone receptor antagonist.
- It is licensed for the treatment of acromegaly in patients who have had an inadequate response to surgery and/or radiation therapy and in whom an appropriate medical treatment with somatostatin analogues did not normalise IGF-I concentrations or was not tolerated.

### **Pre-treatment checks**

- The vial stopper contains natural rubber latex which may cause latex-sensitivity reactions in susceptible individuals.
- Avoid in pregnancy and breast feeding (insufficient information). Reduction in IGF-I concentration may potentially *fertility* in female patients. Women of child-bearing potential should take contraceptive precautions.
- The safety and effectiveness of pegvisomant in patients with renal or hepatic insufficiency has not been established and no dosing recommendations are available.
- Initiate and titrate doses only under the supervision of a physician experienced in the treatment of acromegaly.

### Biochemical and other tests

Liver function: AST; ALT; bilirubin Renal function: U, Cr, CrCl (or eGFR) Serum IGF-I concentrations (the use of commercially available growth hormone assays is not appropriate – see Interactions below)

### Dose

Loading dose: 80 mg by SC injection.

Maintenance dose: the dose is then adjusted (based on serum IGF-I concentration) every 4–6 weeks in increments (or decrements) of 5 mg/day to a suitable maintenance dose (maximum 30 mg daily).

### **Subcutaneous injection**

- 1. Add 1 mL solvent to dry powder vial.
- Gently dissolve the powder with a slow, swirling motion. Do not shake vigorously, as this might cause denaturation of the active ingredient. After reconstitution, vials contain 10 mg/mL, 15 mg/ mL or 20 mg/mL dependent on vial size.
- 3. Discard the product if the resulting solution is cloudy or contains particulate matter.
- 4. Give by SC injection into the upper arm, upper thigh, abdomen or buttocks. Rotate injection sites daily to prevent lipohypertrophy.

# Pentamidine isetionate (pentamidine isethionate)

### 300-mg dry powder vials

- · Pentamidine isetionate is an antiprotozoal agent.
- It is used in the treatment of the early stages of African trypanosomiasis (especially *Trypanosoma brucei gambiense* infections), in some forms of leishmaniasis, and in the treatment and prophylaxis of pneumocystis pneumonia.
- The injection is also licensed for use by nebulisation in the treatment of pneumocystis pneumonia (a ready-made solution for nebulisation also exists).
- Doses are expressed in terms of the base: Pentamidine 1 mg ≈ 1.74 mg pentamidine isetionate.

Pentamidine isetionate is toxic and personnel must be adequately protected during handling and administration – consult product literature.

### **Pre-treatment checks**

- Caution in ↓K, ↓Mg, coronary heart disease, ↓pulse (<50 bpm), history of ventricular arrhythmias, concomitant use with other drugs which prolong QT-interval, ↑BP or ↓BP, pancreatitis, hypergly-caemia or hypoglycaemia, leucopenia, thrombocytopenia or anaemia.</li>
- Ensure that appropriate equipment for maintenance of an adequate airway, other supportive measures and agents (e.g. IV fluids, vasopressor agents) for the management of severe \u03c4BP are readily available.

### Biochemical and other tests

| Blood pressure                | Fasting blood glucose                |
|-------------------------------|--------------------------------------|
| Bodyweight                    | FBC                                  |
| ECG                           | LFTs                                 |
| Electrolytes: serum K, Ca, Mg | Renal function: U Cr, CrCl (or eGFR) |

### Dose

**Pneumocystis jiroveci (Pneumocystis carinii) pneumonia:** 4 mg/kg by IV infusion once daily for at least 14 days. Alternatively give 600 mg via nebuliser once daily for 3 weeks (consult product literature for suitable equipment to be used).

**Prevention of** *Pneumocystis jiroveci* (*Pneumocystis carinii*) **pneumonia:** 300 mg via nebuliser every 4 weeks or 150 mg every 2 weeks.

**Visceral leishmaniasis:** 3–4 mg/kg by IM injection on alternate days to a maximum of 10 injections. A repeat course may be necessary.

**Cutaneous leishmaniasis:** 3–4 mg/kg by IM injection once or twice weekly until the condition resolves.

**Trypanosomiasis:** 4 mg/kg by IM injection or IV infusion once daily or on alternate days for 7–10 doses.

Dose in renal impairment: adjusted according to creatinine clearance:<sup>1</sup>

- CrCl >20-50 mL/minute: dose as in normal renal function.
- CrCl 10-20 mL/minute: dose as in normal renal function.
- CrCl <10 mL/minute: where IV infusion is required, dependent on the severity of the infection, 4 mg/kg/day IV for 7 days then on alternate days to complete a minimum 14 doses or 4 mg/kg on alternate days to complete a minimum 14 doses.

### Intramuscular injection

See Special handling below.

### Preparation

- 1. Reconstitute a vial with 3 mL WFI to give 300 mg/mL.
- 2. Withdraw the require dose and discard any remainder in accordance with local protocol.

### Administration

- 1. Administer with patient lying down (see Monitoring).
- Give by deep IM injection into the buttock using the Z-track technique. Rotate injection sites for subsequent injections.

### Intravenous infusion

See Special handling below.

### Preparation

1. Determine the required dose then reconstitute each vial with a volume of WFI or Gluc 5% to produce a concentration of pentamidine that will give a concentration suitable for delivering this dose, i.e.

| Volume of diluent<br>added                     | 3 mL      | 4 mL     | 5 mL     |
|------------------------------------------------|-----------|----------|----------|
| Approximate<br>concentration of<br>pentamidine | 100 mg/mL | 75 mg/mL | 60 mg/mL |

2. Withdraw the required dose and dilute in 50–250 mL NaCl 0.9% or Gluc 5% and discard any remaining vial contents in accordance with local protocol.

### Administration

- 1. The patient should be lying down (see Monitoring).
- 2. Give by slow IV infusion over 60–120 minutes.

# **Nebulisation**

Consult product literature for detailed guidance on administration and protection of bystanders.

### Risk rating: AMBER

Moderate-risk product: Risk-reduction strategies are recommended.

Score = 4

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

### Reference

1. Ashley C, Currie A, eds. The Renal Drug Handbook, 3rd edn. Oxford: Radcliffe Medical Press, 2009.

# **Bibliography**

SPC Pentacarinat 300 mg (accessed 16 February 2009).

# Pentazocine

### 30 mg/mL solution 1-mL and 2-mL ampoules

- Pentazocine lactate has both opioid agonist and antagonist properties. If used in combination with other opioids it may precipitate withdrawal symptoms including the re-emergence of pain.
- It is used for the treatment of moderate to severe pain.
- Parenteral doses are expressed in terms of the base: Pentazocine 100 mg = 131.6 mg pentazocine lactate.

### **Pre-treatment checks**

- Do not use in patients dependent on opioids (can precipitate withdrawal), in heart failure secondary to chronic lung disease and in acute porphyria.
- Caution in pancreatitis, arterial or pulmonary hypertension, cardiac arrhythmias, myocardial infarction, phaeochromocytoma.
- · Caution in renal and hepatic impairment.

### **Biochemical tests**

LFTs Renal function: U, Cr, CrCl (or eGFR)

### Dose

**Moderate to severe pain:** 30–60 mg by IM or SC injection or 30 mg by IV injection every 3–4 hours when required to a maximum total daily dose of 360 mg. Individual doses should not exceed 1 mg/kg SC or IM, or 500 micrograms/kg IV.

**Dose in renal impairment:** reduce dose or avoid. **Dose in hepatic impairment:** reduce dose or avoid.

# Intramuscular injection (preferred to SC route if repeated doses are to be given)

### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection. Rotate injection sites for subsequent injections.
- 3. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

### Intravenous injection

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 3–5 minutes. It may be diluted to  $10 \,\text{mL}$  with NaCl 0.9% to facilitate slow administration.
- 4. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.
## Subcutaneous injection (only use if other routes are not available – risk of tissue damage)

### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by SC injection.
- 3. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

## Bibliography

SPC Fortral injection 30 mg/mL (accessed 19 January 2009).

## Pethidine hydrochloride (meperidine hydrochloride)

#### 50 mg/mL solution in 1-mL and 2-mL ampoules

- Pethidine hydrochloride is an opioid analgesic.
- It is used to treat moderate to severe acute pain including labour pain. It is also used as a
  preoperative medication and as an adjunct to anaesthesia.
- Pethidine is less potent and has a shorter duration of action than morphine but is also less constipating. It has ↓effect on smooth muscle and biliary pressure compared with morphine, and therefore may be considered a better analgesic for biliary colic and pancreatitis.

## **Pre-treatment checks**

- Do not use in acute respiratory depression, where there is a risk of paralytic ileus, in ↑intracranial pressure and in head injury, in comatose patients and phaeochromocytoma.
- Caution in ↓BP, shock, convulsive disorders, supraventricular tachycardias, atrial flutter, chronic
  obstructive pulmonary disease and acute asthma attack, obstructive or inflammatory bowel

## 668 | Pethidine hydrochloride

diseases, biliary tract diseases, alcoholism, prostatic hyperplasia, myasthenia gravis, hypothyroidism (reduce dose), adrenocortical insufficiency (reduce dose).

- Caution in elderly patients or those of low bodyweight use lower doses; the initial dose should not exceed 25 mg.
- Ensure that resuscitation equipment and naloxone are available, especially for IV administration.

Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure and pulse LFTs Pain score Renal function: U, Cr, CrCl (or eGFR) Respiratory rate

## Dose

Pethidine is no longer considered suitable for the management of chronic pain because of its short duration of action and *†risk* of seizures due to the accumulation of its toxic metabolite norpethidine.

**Acute pain:** 25–100 mg by IM or SC injection or 25–50 mg by slow IV injection repeated after 4 hours if required.

**Obstetric pain:** 50–100 mg by IM or SC injection once contractions are at regular intervals, repeated as required up to a maximum 400 mg in 24 hours.

**Premedication:** 25–100 mg by IM injection 1 hour before procedure.

Dose in renal impairment: adjusted according to creatinine clearance,<sup>1</sup>

- CrCl >20 mL/minute: normal adult dose.
- CrCl 10-20 mL/minute: increase dosing interval to 6-hourly and ↓dose by 25%.
- CrCl <10 mL/minute: avoid if possible. If not, increase dosing interval to 8-hourly and ↓dose by 50%.

Dose in hepatic impairment: reduce dose or avoid.

## Intramuscular injection (preferred to SC route for repeated doses but absorption is variable)

### Preparation and administration

- 1. Withdraw the required dose.
- 2. Ensure that the patient is sitting or lying down.
- 3. Give by IM injection into a large muscle such as the gluteus or the lateral aspect of the thigh; take care to avoid nerve trunks.
- 4. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

## Subcutaneous injection (may be irritant if repeated doses are given)

### Preparation and administration

- 1. Withdraw the required dose.
- 2. Ensure that the patient is sitting or lying down.
- 3. Give by SC injection.
- 4. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

## Intravenous injection (fincidence of adverse effects)

- 1. Withdraw the required dose and dilute to 10 mg/mL using WFI, NaCl 0.9% or Gluc 5%.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

- 3. Ensure that the patient is lying down.
- 4. Give by slow IV injection over a minimum of 2–3 minutes.
- 5. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

## Monitoring

Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

# Phenobarbital sodium (phenobarbitone sodium)

## 200 mg/mL solution in 1-mL ampoules (other strengths may be available)

- Phenobarbital sodium is a long-acting barbiturate.
- It is sometimes used as an antiepileptic for the treatment of tonic-clonic and partial seizures. To
  prevent rebound seizures in patients maintained on the drug, withdrawal should be gradual.
- The use of parenteral therapy may have a place in patients normally maintained on phenobarbital when the oral route is temporarily unavailable.
- · It may also used parenterally for the treatment of status epilepticus after other methods have failed.

## **Pre-treatment checks**

- · Avoid in severe respiratory depression, acute porphyria and severe hepatic impairment.
- Caution in elderly patients or those of low bodyweight, senile patients, debilitated patients, history of drug or alcohol abuse, renal impairment.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure and pulse FBC LFTs Pregnancy test (when appropriate) Renal function: U, Cr, CrCl (or eGFR)

## Dose

**Patients previously established on oral therapy:** oral therapy has good bioavailability and therefore parenteral replacement doses should be close to the previous oral dose (e.g. between 75% and 100% of the oral dose) with the same dose frequency, preferably by IV route. Review for signs of toxicity if parenteral therapy is prolonged.

**Status epilepticus:** 10 mg/kg by IV injection up to maximum 1 g. Up to 30 minutes may be required for maximum effect – allow sufficient time for the therapeutic effect to develop before giving additional doses. Do not use in patients who have recently received oral phenobarbital or primidone.

**Dose in renal impairment:** if CrCl < 10 mL/minute reduce the dose by 25–50% avoiding large single doses.<sup>1</sup>

Dose in hepatic impairment: reduce dose and avoid if severe.

## Intravenous injection

### Preparation and administration

- 1. Withdraw the required dose and dilute each 1 mL of injection to 10 mL with WFI.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection at a rate of not more than 100 mg/minute. Care must be taken to avoid inadvertent intra-arterial injection as this may cause spasm, severe pain and tissue damage. Stop injection if patches of discoloured skin or a white hand with cyanosed skin are seen, or if the patient complains of pain.

## Intramuscular injection

Avoid this route if possible; absorption is likely to be delayed from IM sites, and injection-site reactions are likely.

## 672 | Phenobarbital sodium

- 1. Withdraw the required dose. May be further diluted with WFI if required.
- 2. Give by deep IM injection into a large muscle.

## Bibliography

SPC Phenobarbital Sodium Injection BP 200 mg/mL, Martindale Pharmaceuticals (accessed 17 March 2009).

## Phenoxybenzamine hydrochloride

#### 50 mg/mL solution in 2-mL ampoules

- Phenoxybenzamine hydrochloride is a powerful alpha-adrenoceptor blocker with a prolonged duration of action.
- It is used in the management of phaeochromocytoma to control the hypertension associated with excessive catecholamine release.
- It is also licensed for use as an adjunct in the treatment of severe shock not responding to conventional therapy in the presence of an adequate circulatory blood volume.

## **Pre-treatment checks**

- Avoid if there is a history of cerebrovascular accident and during the recovery period after myocardial infarction (usually 3–4 weeks); and in acute porphyria.
- Do not use in hypovolaemia in patient with severe shock.
- · Take care not to cause extravasation (irritant to muscle tissues).
- · Intensive care facilities and facilities for rapid infusion of IV fluid should be available.
- Phenoxybenzamine is carcinogenic in rats and should only be used after very careful consideration
  of the risks, in patients where alternative treatment is inappropriate.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure Bodyweight Renal function: U, Cr, CrCl (or eGFR)

### Dose

Intensive monitoring is required: phenoxybenzamine should only be given in a critical care facility.

**Phaeochromocytoma**: initially 1 mg/kg by IV infusion in 200 mL NaCl 0.9% over 2 hours. Dose may be titrated as necessary. No more than one dose should be given in any 24-hour period. **Shock**: 1 mg/kg by IV infusion in 200–500 mL NaCl 0.9% over not less than 2 hours. No more than one dose should be given in any 24-hour period.

## Intermittent intravenous infusion

See Special handling below.

- 1. Withdraw the required dose and add to the appropriate volume of NaCl 0.9% as described above.
- The solution should be clear and almost colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Patient should be recumbent and BP must be checked every few minutes during infusion.
- Give by IV infusion into a large vein via a volumetric infusion device over at least 2 hours (and a maximum of 4 hours).

## Bibliography

SPC Dibenyline injection concentrate (accessed 21 August 2009).

## Phentolamine mesilate

### 10 mg/mL solution in 1-mL ampoules

- output and has a positive inotropic effect. It reportedly has little effect on the BP of patients with essential hypertension.
- · It is used in the diagnosis of phaeochromocytoma, and also to treat hypertensive episodes due to phaeochromocytoma, e.g. during surgery.
- · It may also be used (unlicensed) in erectile dysfunction and extravasation of noradrenaline (norepinephrine).

## **Pre-treatment checks**

- Do not use in ↓BP, history of MI, coronary insufficiency, angina, or other evidence of coronary artery disease.
- · Caution if a history of peptic ulcer may cause exacerbation.
- · For diagnosis of phaeochromocytoma: antihypertensive drugs are withheld until BP returns to the untreated, hypertensive level; sedatives, analgesics and all other medications except those that might be deemed essential are withheld for at least 24 hours, and preferably 48-72 hours, prior to the test. The test is **not** performed on a patient who is normotensive.

## Biochemical and other tests

Blood pressure: in diagnosis of phaeochromocytoma the patient must be kept at rest and lying down throughout the test preferably in a quiet, darkened room. The injection should be delayed until BP is stabilised, i.e. BP is taken every 10 minutes for at least 30 minutes. Electrolytes: serum K

## Dose

**Management of hypertensive episodes in patients with phaeochromocytoma** (e.g. perisurgery): 2–5 mg by IV injection repeated as necessary. Use a lower dose in elderly patients or those of low bodyweight in case of undiagnosed coronary insufficiency.

**Diagnosis of phaeochromocytoma**: 5 mg by IV or IM injection. See product literature for full details of test procedure and interpretation.

**Serious hypertensive conditions associated with excess circulating catecholamines (unlicensed):** 2–5 mg by IV injection repeated as necessary. Use a lower dose in elderly patients or those of low bodyweight in case of undiagnosed coronary insufficiency.

**Extravasation of noradrenaline (unlicensed):** infiltrate the affected area with 5–10 mg phentolamine diluted to 10–15 mL with NaCl 0.9%. This has been shown to be effective in treating dermal necrosis and sloughing if given within 12 hours of extravasation.

**Prevention of dermal necrosis during infusion of noradrenaline (unlicensed):** 10 mg (1 mL) phentolamine has been added to each 1 L of noradrenaline infusion.

## Intravenous injection

Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration.
- 3. Give by rapid IV injection.

## Intramuscular injection

- 1. Withdraw the required dose.
- 2. Give by IM injection.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

## Bibliography

SPC Rogitine ampoules 10 mg (accessed 26 June 2009).

## Phenylephrine hydrochloride

## 10 mg/mL solution in 1-mL ampoules

- Phenylephrine hydrochloride is a sympathomimetic with mainly alpha-adrenergic activity.
- It is licensed for the treatment of hypotensive states, e.g. circulatory failure, during spinal anaesthesia or drug-induced *LBP*.
- · It has also been used to treat priapism (unlicensed).

## **Pre-treatment checks**

- Avoid in severe ↑BP and hyperthyroidism.
- Do not give with MAOIs, or within 14 days of ceasing such treatment.
- Caution in patients with pre-existing cardiovascular disease such as ischaemic heart disease, arrhythmias, occlusive vascular disease including arteriosclerosis, 

  BP or aneurysms. Anginal pain may be precipitated in patients with angina pectoris.
- · Caution in patients with diabetes mellitus or closed-angle glaucoma.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure TFTs

## Dose

The route of administration should be determined by the needs of the individual patient; patients who are in shock may require IV administration to ensure absorption of the drug.

**By SC or IM injection:** 2–5 mg, with further doses of 1–10 mg if necessary according to response. **By slow IV injection:** 100–500 micrograms, repeated as necessary after a minimum of 15 minutes. **By IV infusion:** initially at a rate of up to 180 micrograms/minute, reduced according to response to 30–60 micrograms/minute.

## **Subcutaneous injection**

## Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by SC injection.

## Intramuscular injection

### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

## Intravenous injection

### Preparation and administration

The initial dilution of this injection produces more than the required dose. Adjust the volume before administration.

- 1. Withdraw 0.1 mL (1 mg) and dilute to 1 mL with WFI.
- 2. Cap the syringe and mix well to give a solution containing 1 mg/mL (1000 micrograms/mL).
- 3. Expel the excess solution from the syringe so that the prescribed dose remains.

## 680 | Phenylephrine hydrochloride

- 4. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by slow IV injection over 3-5 minutes.

## **Continuous intravenous infusion**

## Preparation and administration

- 1. Withdraw 10 mg (1 mL) and add to 500 mL NaCl 0.9% or Gluc 5%.
- 2. Mix well to give a solution containing 20 micrograms/mL.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV infusion via a volumetric infusion device at an initial rate of 180 micrograms/minute (540 mL/hour). Adjust the rate to clinical response: usually 30–60 micrograms/minute (90– 180 mL/hour).

| Common and serious<br>undesirable effects | ↑BP, headache, arrhythmias, peripheral ischaemia, ↑pulse or reflex ↓pulse.                                                                                                                                                                                                                            |  |
| Pharmacokinetics                          | Elimination half-life is 2-3 hours. When injected SC or IM, phenylephrine takes 10-15 minutes to act and effects last for up to 1 or 2 hours respectively. IV injections are effective for up to about 20 minutes.                                                                                    |  |
| Significant<br>interactions               | <ul> <li>The following may ↑phenylephrine levels or effect (or ↑side-effects):<br/>MAOIs (risk of hypertensive crisis), moclobemide (risk of hypertensive crisis),<br/>rasagiline (avoid combination).</li> <li>Phenylephrine may ↓levels or effect of guanethidine (↓hypotensive effect).</li> </ul> |  |
| Action in case of<br>overdose             | No known antidote. Treatment should consist of symptomatic and supportive<br>measures.<br>The hypertensive effects may be treated with an alpha-adrenoceptor blocking<br>drug, e.g. phentolamine (see the Phentolamine monograph).                                                                    |  |
|                                           |                                                                                                                                                                                                                                                                                                       |  |

## Bibliography

SPC Phenylephrine Injection BP 10 mg/mL, Sovereign Medical (accessed 21 August 2009).

## **Phenytoin sodium**

## 50 mg/mL solution in 5-mL ampoules

- Phenytoin sodium is a hydantoin antiepileptic agent believed to act by preventing the spread of seizure activity, rather than by raising seizure threshold.
- It is used parenterally in the management of status epilepticus and for prophylactic control of seizures in neurosurgery or following serious head injury.
- Phenytoin therapy should not be withdrawn abruptly as this may precipitate seizures and status
  epilepticus: may be used parenterally in patients normally maintained on phenytoin when the oral
  route is temporarily unavailable.
- Phenytoin sodium is also licensed for use in cardiac arrhythmias, but this use is now obsolete.
- · Injection doses are expressed in terms of phenytoin sodium.

## **Pre-treatment checks**

- · Ensure that resuscitation facilities are available.
- Avoid in acute porphyria.
- Caution in JBP, Jpulse, heart failure, previous myocardial infarction, sinoatrial block, second- and third-degree heart block and Stokes-Adams syndrome.

#### *Biochemical and other tests (not all are necessary in an emergency situation)*

| Blood pressure | FBC                    |
|----------------|------------------------|
| Bodyweight     | LFTs including albumin |
| ECG            | Pregnancy test         |

## Dose

#### **Status epilepticus:**

- Loading dose (in patients not maintained on oral phenytoin): 18 mg/kg, by slow IV injection or infusion. Blood levels may be checked 2 hours after giving the loading dose to ensure that they are in the correct range.
- *Maintenance dose:* Up to 100 mg every 6–8 hours. Adjust maintenance dose according to plasma levels.

**Maintenance in patients temporarily unable to take oral therapy:** the maintenance dose may be given as a single daily infusion, or in divided doses (see information below)

#### For existing epilepsy patients switched from oral maintenance to parenteral dosing

- Capsules (containing phenytoin sodium)  $100 \text{ mg} \equiv 100 \text{ mg}$  phenytoin sodium IV.
- Suspension (containing phenytoin base)  $90 \text{ mg} \cong 100 \text{ mg}$  phenytoin sodium IV.
- Maintenance therapy by the IM route is not recommended as absorption is slow and erratic. However, if use of the IM route is deemed essential, the manufacturers advise increasing the usual oral dose by 50%. The IM route is not usually used for longer than 1 week. When oral therapy is resumed, reduce usual oral dosage by 50% for the same amount of time the patient was receiving IM therapy. This may ↓risk of accumulation as residual phenytoin is released from IM injection sites.
- Phenytoin exhibits non-linear pharmacokinetics (minor dose changes can have a significant effect on phenytoin levels) always monitor levels closely when route is changed.

#### Intramuscular dosing: not advised - see notes above.

**Dose in hepatic impairment:** a reduced maintenance dose may be adequate to control seizures. Monitor levels closely.

## Intravenous injection

- 1. Withdraw the required dose.
- The solution should be clear and colourless to faintly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Flush with NaCl 0.9% before administration.
- 4. Give by slow IV injection into a large vein (using a syringe pump if necessary) at a maximum rate of 25 mg/minute (to avoid ↓BP). The rate of administration may be further reduced in higher-risk patients to 5–10 mg/minute (e.g. elderly patients or those of low bodyweight and those with heart disease).
- After administration, flush with NaCl 0.9% to reduce the risk of irritation (phenytoin is highly alkaline).

## Intermittent intravenous infusion

Phenytoin sodium is incompatible with Gluc 5%, Gluc-NaCl, Hartmann's, Ringer's. Stability is limited in NaCl 0.9% (precipitates may form). ECG monitoring during IV administration is strongly advised: risk of serious arrhythmias.

#### Preparation and administration

- 1. Doses may be given as undiluted injection via syringe pump because this reduces the likelihood of precipitation that is seen when using dilutions in NaCl 0.9%. This practice is commonplace though unlicensed.
- 2. Alternatively, withdraw the required dose and add to 50–100 mL of NaCl 0.9% (maximum concentration 10 mg/mL).
- 3. The solution should be clear and colourless to faintly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Flush the line with NaCl 0.9% before administration.
- 5. Give by IV infusion into a large vein (via a 0.22–0.50-micron in-line filter if using diluted solution) using a volumetric infusion device. The rate of infusion should be no more than 25 mg/minute (to avoid ↓BP). The rate of administration may be further reduced in higher-risk patients to 5–10 mg/minute (e.g. elderly patients or those of low bodyweight and those with heart disease).
- 6. Throughout the infusion inspect for particulate matter and discoloration.
- 7. After administration, flush with NaCl 0.9% to reduce risk of irritation.

## Intramuscular injection (not recommended)

Maintenance therapy by the IM route is not recommended as absorption is slow and erratic (see information above).

- 1. Withdraw the required dose.
- 2. Give by deep IM injection. SC injection should be avoided because of the risk of tissue necrosis.

## **Additional information**

Common and serious Injection/infusion-related:
 Too rapid administration: Arrhythmias, ⊥pulse, heart block, vasodilation, ⊥BP, cardiovascular collapse, asystole, impaired respiratory function and respiratory arrest.
 Local: Injection-site reaction or pain. Inadvertent SC, intra-arterial or perivascular injection may cause severe local tissue damage due to the high pH. Other: Nausea, vomiting, constipation, anorexia, insomnia, transient nervousness, tremor, paraesthesia, dizziness, headache, peripheral neuropathy, dyskinesia, rash, megaloblastic anaemia, leucopenia, thrombocytopenia, aplastic anaemia, hepatotoxicity, lymphadenopathy, polyarteritis nodosa, lupus erythematosus, Stevens-Johnson syndrome, toxic epidermal necrolysis, pneumonitis, interstitial nephritis.

## Additional information (continued)

| Elimination half-life is 13-46 hours. The half-life may increase if the metabolism<br>pathway becomes saturated - risk of toxicity.<br>Phenytoin is highly protein bound (about 90% and mainly to albumin).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### Risk rating: AMBER

Moderate-risk product: Risk-reduction strategies are recommended.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

## **Phosphates**

#### Solution in 500-mL Polyfusor infusion container

- Phosphorus plays an important part in the structure of bones and teeth and, as adenosine triphosphate, is crucial in the transfer of cellular energy.
- Normal range for plasma phosphate: 0.8–1.44 mmol/L.

Phosphates solution 500 mL contains: 50 mmol phosphate 81 mmol sodium 9.5 mmol potassium

## **Pre-treatment checks**

- Avoid in  $\uparrow PO_4$ ,  $\uparrow K$ ,  $\uparrow Na$ ,  $\downarrow Ca$  or over-hydration.
- Caution in patients with cardiac disease, ↑BP, peripheral or pulmonary oedema, renal impairment and pre-eclampsia.
- · Care with patients on potassium-sparing diuretics.

Biochemical and other tests (not all are necessary in an emergency situation)

| Acid-base balance | Electrolytes: serum K, Na, Ca, PO <sub>4</sub> |
|-------------------|------------------------------------------------|
| Blood pressure    | Fluid balance                                  |
| Bodyweight        | Renal function: U, Cr, CrCl (or eGFR)          |
| ECG               |                                                |

### Dose

The doses below are as advised by the manufacturer; however, IV phosphates are associated with serious adverse effects if hypophosphataemia is over-corrected.

Some authorities advise giving no more than 9 mmol (90 mL) phosphate over 12 hours (7.5 mL/ hour) unless given within a critical care facility.

**Moderate hypophosphataemia:**  $0.1-0.2 \text{ mmol/kg} \equiv 1-2 \text{ mL/kg}$  by IV infusion over 6-12 hours. **Severe hypophosphataemia:**  $0.2-0.5 \text{ mmol/kg} \equiv 2-5 \text{ mL/kg}$  by IV infusion over 6-24 hours up to a maximum of 50 mmol (500 mL) per infusion. Repeat as necessary over subsequent days in response to phosphate levels.

**Dose in renal impairment:** reduce the dose in elderly patients or those of low bodyweight with renal impairment.

Dose in hepatic impairment: no information available.

## Intermittent intravenous infusion

- 1. The infusion is pre-prepared for use. It should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV infusion over 12 hours at a maximum rate of 7.5 mL/hour (see warning above) unless given within a critical care facility.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

## **Bibliography**

SPC Phosphates Polyfusor (accessed 14 October 2009).

## Phytomenadione (vitamin K<sub>1</sub>, phytonadione)

#### 10 mg/mL solution (mixed micelles vehicle) in 0.2-mL and 1-mL ampoules

This monograph refers to the mixed micelles formulation available in the UK. Information given does not apply to formulations containing polyoxyl castor oil, which can cause severe hypersensitivity reactions if given IV.

- Vitamin K is an essential cofactor in the hepatic synthesis of prothrombin (factor II) and other blood clotting factors (factors VII, IX, and X, and proteins C and S). It has a role in the function of proteins such as osteocalcin that are important for bone development.
- Phytomenadione is a naturally occurring vitamin K substance used to reverse *\`*INR and haemorrhage caused by warfarin. It can be used IV or the injectable preparation can be given orally for this indication.
- Phytomenadione may be used to reverse *î*INR and haemorrhage caused by phenindione therapy. It
  may also be used to reverse acenocoumarol (nicoumalone) but may have a lesser effect. It is not
  effective as a heparin antidote (see the Protamine sulfate monograph).
- Phytomenadione is also indicated in the treatment of haemorrhage or threatened haemorrhage associated with a low blood level of prothrombin or factor VII.

## **Pre-treatment checks**

Time to onset of action is a minimum of 1–2 hours if given IV, irrespective of dose, and 6–10 hours if given orally. If a faster response is needed, prothrombin complex concentrate (factors II, VII, IX, and X) 30–50 units/kg or (if no concentrate available) fresh frozen plasma 15 mL/kg should also given.

## Biochemical and other tests

LFTs Prothrombin time or INR

### Dose

Parenterally, for the mixed micelles formulation the IV route is preferred (see caution above) because absorption is irregular if given IM, and there is a risk of haematoma formation. SC delivery is reported to be less effective in treating over-anticoagulation.

#### As an antidote to warfarin (or other 4-hydroxycoumarin):

- Major bleeding: stop warfarin; give phytomenadione 5-10 mg by slow IV injection.
- Larger doses of up to 40 mg in 24 hours have been given but this can cause considerable delay when anticoagulant therapy is planned. If anticoagulation is needed following overdosage of phytomenadione, heparin may be used.

- INR >8.0, no bleeding or minor bleeding: stop warfarin, restart when INR <5.0; if there are other risk
  factors for bleeding, give phytomenadione 500 micrograms by slow IV injection or 5 mg orally (for
  partial reversal of anticoagulation give smaller oral doses of phytomenadione, e.g. 0.5–2.5 mg
  orally); repeat the dose of phytomenadione if INR is still too high after 24 hours.</li>
- INR <8.0: stop warfarin, restart when INR<5.0; phytomenadione is unnecessary unless there is bleeding (in which case investigate the possibility of underlying pathology).

**To reverse raised INR associated with liver impairment:** give 10 mg IV and monitor INR to assess the need for further doses; if using the oral route, water-soluble menadiol sodium phosphate is more effective.

## Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear to slightly opalescent and pale yellow. Inspect visually for particulate matter or discoloration prior to administration.
- 3. Give by IV injection over 3-5 minutes.

## Intermittent intravenous infusion

## Preparation and administration

- 1. Withdraw the required dose and add to 50 mL Gluc 5%.
- The solution should be clear to slightly opalescent and pale yellow. Inspect visually for particulate matter or discoloration prior to administration.
- 3. Give by IV infusion over 15-30 minutes.

## Oral use (use unlicensed in adults)

Konakion MM and Konakion MM Paediatric are identical formulations<sup>1</sup>: either preparation may be used.

- 1. Withdraw the required dose using an oral syringe.
- 2. Place the dose directly into the patient's mouth.

## Piperacillin with tazobactam

### 2.25-g and 4.5-g dry powder vials

- Piperacillin is a ureidopenicillin. It is given in combination with the beta-lactamase inhibitor tazobactam to widen its spectrum of action.
- The combined preparation is used in the treatment of severe infections including neutropenic sepsis, peritonitis and septicaemia.
- Doses of piperacillin are expressed in terms of the base: Piperacillin  $1 g \equiv 1.04 g$  piperacillin sodium.
- Piperacillin with tazobactam doses are expressed below as the combined mg of the two constituents:

Piperacillin with tazobactam  $4.5 \text{ g} \equiv \text{piperacillin } 4 \text{ g}$  with tazobactam 500 mg.

#### MHRA advice (January 2009)

Generic piperacillin/tazobactam products have different compatibilities with other medicines compared with Tazocin, raising a risk of serious medication errors. Generic piperacillin/tazobactam must not be mixed or co-administered with any aminoglyco-side, and must not be reconstituted or diluted with Hartmann's solution.

## Pre-treatment checks

- · Check for history of allergy/hypersensitivity to any beta-lactam drug or beta-lactamase inhibitors.
- Patients to be treated for gonorrhoea should be evaluated for syphilis (it may mask or delay the symptoms of incubating syphilis).

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Electrolytes: serum K | LFTs                                  |
|-----------------------|---------------------------------------|
| FBC                   | Renal function: U, Cr, CrCl (or eGFR) |

## Dose

Standard dose: 2.25-4.5 g every 6-8 hours, usually 4.5 g every 8 hours.

**Neutropenic sepsis** (in combination with an aminoglycoside, but see above): 4.5 g every 6 hours. Neutropenic patients with signs of infection (e.g. fever) should receive immediate empirical antibiotic therapy before laboratory results are available.

Dose in renal impairment: adjusted according to creatinine clearance:<sup>1</sup>

- CrCl >20-50 mL/minute: dose as in normal renal function.
- CrCl 10-20 mL/minute: 4.5 g every 8-12 hours, or 2.25 g every 6 hours.
- CrCl <10 mL/minute: 4.5 g every 12 hours, or 2.25 g every 8 hours.

## Intravenous injection

Preparation and administration

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

## 692 | Piperacillin with tazobactam

- 1. Reconstitute each 2.25-g vial with 10 mL WFI or NaCl 0.9% (each 4.5-g vial requires 20 mL) and swirl until dissolved. This may take up to 10 minutes depending on brand.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present (it is not uncommon with this preparation to find small particles of the bung to be forced into the ampoule).
- 3. Give by IV injection over at least 3-5 minutes.

## Intravenous infusion

#### Preparation and administration

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

NB: some manufacturers' vials may be 'docked' for reconstitution with a 'minibag plus'.

- 1. Reconstitute each 2.25-g vial with 10 mL WFI or NaCl 0.9% (each 4.5-g vial requires 20 mL) and swirl until dissolved. This may take up to 10 minutes depending on brand.
- 2. Add to 50-100 mL of compatible infusion fluid (usually NaCl 0.9%).
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present (it is not uncommon with this preparation to find small particles of the bung that have been forced into the vial).
- 4. Give by IV infusion over 20-30 minutes.

## **Technical information** Incompatible with Piperacillin with tazobactam is incompatible with Hartmann's. Sodium bicarbonate. Amikacin, amiodarone, amphotericin, chlorpromazine, cisatracurium, dobutamine, drotrecogin alfa (activated), ganciclovir, gentamicin, tobramycin, vancomycin. Compatible with Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, WFI Y-site: Brands vary pН 5.7 Sodium content 5.6 mmol/2.25 g; 11.2 mmol/4.5 g Storage Store below 25°C in original packaging. Displacement value 1.6 mL for every 2.25 g; 3.2 mL for every 4.5 g Stability after From a microbiological point of view, should be used immediately; however: preparation Reconstituted vials may be stored at 2-8°C for 24 hours. Prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours.

## 694 | Piperacillin with tazobactam | Pipotiazine palmitate

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

## Pipotiazine palmitate (pipothiazine palmitate)

#### 50 mg/mL oily solution in 1-mL and 2-mL ampoules

- Pipotiazine palmitate is a phenothiazine antipsychotic with a wide range of actions. It is a dopamine inhibitor; it has antiemetic activity; it has muscle relaxant properties; and it inhibits the heat-regulating centre.
- · It is used as a long-acting depot injection in the treatment of schizophrenia and other psychoses.

## **Pre-treatment checks**

- Do not use in comatose states, including alcohol, barbiturate, or opiate poisoning.
- Do not use if there is severe renal or hepatic impairment, in phaeochromocytoma, or in patients with marked cerebral atherosclerosis or severe cardiac insufficiency.
- Caution in epilepsy, Parkinson disease, liver disease, renal failure, cardiac disease, depression, myasthenia gravis, prostatic hypertrophy, narrow-angle glaucoma, hypothyroidism, hyperthyroidism, severe respiratory disease or if there are risk factors for stroke.
- · Concomitant administration with other antipsychotics should be avoided.

### Biochemical and other tests

| Blood pressure | FBC            |
|----------------|----------------|
| Bodyweight     | LFTs           |
| ECG            | Renal function |

### Dose

**Test dose:** 25 mg by IM injection to assess tolerability. Reduce dose to 5–10 mg if patient is elderly. **Maintenance dose:** 25–50 mg to be administered at least 4–7 days after test dose; the usual dose range is 50–100 mg every 4 weeks. Some patients may require up to 200 mg every 4 weeks.

## Intramuscular injection

- 1. Withdraw the required dose.
- 2. Give by deep IM injection into the gluteal muscle. Volumes >2 mL should be distributed between two injection sites. Rotate injection sites for subsequent injections.

## **Piroxicam**

#### 20 mg/mL solution 1-mL ampoules

- · Piroxicam is a non-steroidal anti-inflammatory drug (NSAID).
- It is licensed for symptomatic relief of osteoarthritis, rheumatoid arthritis or ankylosing spondylitis.

#### CHMP advice (June 2007)

- The maximum dose of piroxicam should be 20 mg per day.
- It should only be initiated by physicians experienced in treating inflammatory or degenerative rheumatic diseases.
- Piroxicam should not be used as first line treatment and should not be used for acute, painful
  and inflammatory conditions.

## **Pre-treatment checks**

- Avoid in active peptic ulceration, history of recurrent ulceration, severe heart failure, asthma
  induced by aspirin or other NSAIDs, nasal polyps, angioedema or urticaria.
- · Caution in elderly patients or those of low bodyweight, and in renal and hepatic impairment.
- Consider prescribing a gastro-protective agent.

### Biochemical and other tests

| Blood pressure | LFTs                                  |
|----------------|---------------------------------------|
| FBC            | Renal function: U, Cr, CrCl (or eGFR) |

## Dose

**Standard dose:** 20 mg daily. **Dose in renal impairment:** avoid if possible.

## Intramuscular injection

### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by deep IM injection into the upper outer quadrant of the buttock.

## **Bibliography**

SPC Feldene (accessed 16 October 2008).

## **Potassium chloride**

20 mmol (1.5 g)/L in NaCl 0.9%, Gluc 5%, or Gluc-NaCl solution in 500-mL and 1-L infusion containers

40 mmol (3 g)/L in NaCl 0.9%, Gluc 5%, or Gluc-NaCl solution in 500-mL and 1-L infusion containers

Concentrated solutions (restricted use):

20 or 40 mmol in 100-mL NaCl 0.9% infusion bags

20mmol/10mL (1.5g/10mL; 15%) ampoules - other strengths may be available

- · Potassium is the major intracellular electrolyte.
- Normal range for serum potassium: 3.5–5.0 mmol/L.
- Potassium is given IV as the initial treatment for the correction of severe  $\downarrow K$  (<2.5 mmol/L) and for treatment and prevention of  $\downarrow K$  where the oral route is unavailable.
- Pre-prepared solutions containing up to 40 mmol/L KCl are considered safe for routine use in general clinical areas; more concentrated solutions should only be used in critical care with intensive monitoring because of the risk of arrhythmias and asystole.
- Potassium chloride  $3 g \equiv 20 \text{ mmol of } K^+$  and  $Cl^-$ .

#### The UK NPSA Patient Safety Alert (Oct 2002)

Potassium chloride concentrate solution can be fatal if given inappropriately, therefore:

- Commercially prepared ready to use dilute solutions containing potassium chloride should be used wherever possible.
- If a suitable solution is not available commercially, dilutions should be made in the hospital pharmacy wherever possible.
- Storage of concentrated potassium chloride solutions should be restricted to pharmacy departments and to those critical care areas where concentrated solutions are needed for urgent use.
- Receipt and use of these solutions should be recorded in a similar way to Controlled Drugs and stocks should be kept in a separate locked cupboard away from commonly used diluting solutions.
- Potassium chloride concentrate solution should not be transferred between clinical areas.

## **Pre-treatment checks**

- · Potassium chloride concentrate must not be injected undiluted as instant death may occur.
- Do not give in cases of  $\uparrow$ K,  $\uparrow$ Cl or if CrCl <10 mL/minute.
- Caution in cardiac disease or conditions predisposing to ↑K such as renal or adrenocortical insufficiency, acute dehydration, and extensive tissue destruction as occurs with severe burns and in patients who are receiving potassium-sparing diuretics or other medications that may ↑K.
- In cases of renal insufficiency due to severe dehydration, excretory function should be restored by correction of the fluid deficit in order to ensure adequate urinary excretion of potassium before its parenteral administration.
- Initial potassium replacement therapy should not involve glucose infusions, because glucose may further decrease serum K.

Biochemical and other tests (not all are necessary in an emergency situation)

ECG Electrolytes: serum K, Cl Renal function: U, Cr, CrCl (or eGFR)

## Dose

**Treatment of hypokalaemia:** the dose is dependent upon the biochemistry and clinical condition of the patient.

**Mild to moderate**  $\downarrow$ **K (K** > **2.5 mmol/L):** oral KCl supplements are usually adequate. If the oral route is temporarily unavailable, a single dose of 20–40 mmol by IV infusion over 6–8 hours may be sufficient to treat acute deficiency.

Severe  $\downarrow$ K (K < 2.5 mmol/L): 20–40 mmol (as a 40 mmol/L solution) by IV infusion at a maximum rate of 20 mmol/hour (10 mmol/hour is the usual maximum in a general ward area) governed by the clinical status and hydration of the patient. Repeat as necessary according to biochemistry results.

More concentrated solutions may be given in a critical care area with ECG monitoring, particularly where fluid overload is problematic.

NB: There is a high risk of asystole if the administration rate reaches 40 mmol/hour.

**Prevention of hypokalaemia where the oral route is unavailable:** average adult requirement is considered to be approximately 1 mmol/kg/day by IV infusion although this may rise to 2–3 mmol/kg/day where there are large losses such as those from drains, fistulae, etc.

## **Continuous intravenous infusion**

Preparation and administration

Check that you have selected the correct strength of KCl-containing infusion fluid. Owing to the risk of thrombophlebitis, solutions containing >30 mmol/L should be given via the largest vein available.

- 1. The infusion is pre-prepared for use\*. It should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 2. Give by IV infusion via a volumetric infusion device at a maximum rate of 10–20 mmol/hour (10 mmol/hour is the usual maximum in a general ward area) unless the patient is being treated under specialist supervision in a critical care area. Owing to the risk of thrombophlebitis, solutions containing >30 mmol/L should be given via the largest vein available.
- 3. Discard any unused portion. Do not reconnect partially used infusion containers.

\**Important*: If a pre-prepared infusion is not available at the required strength, and it is necessary to add concentrated KCl to an infusion fluid:

- Additions must never be made to an infusion container that has already been connected to a giving set.
- After the correct quantity of KCl has been added mix thoroughly by squeezing and inverting the bag at least 10 times.
- KCl is particularly prone to a 'layering' effect when added without adequate mixing: a concentrated layer of KCl will form at the bottom of the bag, which may cause the patient to receive an inadvertent bolus.

Give calcium gluconate to stabilise the myocardium and insulin/glucose to lower serum K rapidly. Salbutamol has also been used but its use is controversial. See relevant entries. Review all potassium-retaining medication. |  |

Risk rating: RED

Scoring system not suitable for this substance. *Caution:* Extreme risk posed by inappropriate IV administration.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# **Pralidoxime**

#### 1-g dry powder vial (from designated centres)

- Pralidoxime chloride is a cholinesterase reactivator.
- It is used (unlicensed) as an adjunct to atropine in the treatment of poisoning due to organophosphorus chemicals.
- It is available from designated centres in the UK see Toxbase at www.toxbase.org for this list.

## **Pre-treatment checks**

- Do not use in the treatment of poisoning due to phosphorus, inorganic phosphates or organophosphates not having anticholinesterase activity.
- Use with caution in myasthenia gravis as it may cause a myasthenic crisis.
- Morphine, theophylline, aminophylline, and suxamethonium are contraindicated in organophosphorus poisoning. Avoid tranquillisers such as reserpine or phenothiazines.
- Pralidoxime should be administered within 36 hours after termination of exposure to the organophosphate. However, if the poison was ingested, exposure will continue for some time owing to the slow absorption from the lower bowel.
- If the skin has been exposed, clothing should be removed and the hair and skin washed thoroughly with sodium bicarbonate, alcohol or a washing-up liquid solution as soon as possible.
- · Use with caution in renal impairment.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure and pulse Bodyweight Red blood cell, plasma cholinesterase and urinary paranitrophenol (if exposed to parathion) will aid diagnosis and help monitor progress, but do not wait for results before initiating treatment.

Renal function: U, Cr, CrCl (or eGFR)

#### Dose

It is essential to consult a poisons information service, e.g. Toxbase at www.toxbase.org (password or registration required) for full details of the management of organophosphorus poisoning.

#### Organophosphorus poisoning (unlicensed)<sup>1</sup>

**Loading dose:** 30 mg/kg by IV infusion over 20 minutes. In patients weighing 60–80 kg this dose can be rounded up or down to 2 g.

**Subsequent dose:** 8 mg/kg/hour by IV infusion. In patients weighing 60–80 kg this can be rounded up or down to 0.5 g/hour. Usual maximum dose is 12 g in 24 hours. Continue treatment until the patient has not required atropine treatment for at least 12 hours; treatment may be required for several days.

**Fluid restriction:** if pulmonary oedema is present, the loading dose may be given by IV injection. **Dose in renal impairment:** pralidoxime is renally excreted therefore dose reduction is probably required, particularly for prolonged infusions, but little information available.

# Intravenous infusion (loading dose)

- 1. Reconstitute each 1-g vial with 20 mL WFI.
- 2. Withdraw required dose and add to 100 mL NaCl 0.9%.

- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 20 minutes.

# Continuous intravenous infusion (subsequent dosing)

## Preparation and administration

- 1. The aim is to produce a solution containing 1–2% pralidoxime in NaCl 0.9% (e.g. 10 g could be made up to 500 mL).
- 2. Withdraw 20 mL for each vial to be used from an infusion bag containing the desired final volume of NaCl 0.9% and discard.
- 3. Reconstitute each 1-g vial with 20 mL WFI.
- Withdraw required total dose and add to the prepared infusion bag to give a solution containing 1–2% pralidoxime. Mix well.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 6. Give by IV infusion using a volumetric infusion device at the required rate (see Dose above).
- 7. Prepare a fresh infusion bag at least every 24 hours.

# Intravenous injection (loading dose if IV infusion is not possible)

## Preparation and administration

- 1. Reconstitute each 1-g vial with 20 mL WFI.
- 2. Withdraw the required dose.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by slow IV injection over 5-10 minutes.

# Prednisolone acetate

#### 25 mg/mL aqueous suspension in 1-mL ampoules

- · Prednisolone acetate is a corticosteroid with mainly glucocorticoid activity.
- It is used in the treatment of conditions for which systemic corticosteroid therapy is indicated (except adrenal-deficiency states). Deep IM injections have a depot effect, allowing dosing once or twice weekly.
- · It may also be given by intra-articular or intrasynovial injection for various inflammatory conditions.
- · Doses for injection are expressed in terms of prednisolone acetate.

# **Pre-treatment checks**

- Avoid where systemic infection is present (unless specific therapy given).
- · Avoid live virus vaccines in those receiving immunosuppressive doses.
- May activate or exacerbate amoebiasis or strongyloidiasis (exclude before initiating a corticosteroid in those at risk or with suggestive symptoms). Fungal or viral ocular infections may also be exacerbated.
- Caution in patients predisposed to psychiatric reactions, including those who have previously suffered corticosteroid-induced psychosis, or who have a personal or family history of psychiatric disorders.
- · Do not inject directly into tendons.

#### Intra-articular:

- Do not inject into unstable joints.
- Do not give in the presence of active infection in or near joints.

# Dose

**Intramuscular:** 25–100 mg once or twice weekly, adjusted according to patient response. **Intra-articular or intrasynovial:** 5–25 mg according to size of joint; not more than three joints should be treated on any one day; where appropriate it may be repeated when relapse occurs.

# Intramuscular injection

#### Preparation and administration

- · Withdraw the required dose.
- Give by IM injection.

# Intra-articular or intrasynovial injection

#### Preparation and administration

- 1. Withdraw the required dose.
- Inject into the affected area. Treatment failure after intra-articular injection is most frequently the result of failure to enter the joint space.

# Bibliography

SPC Deltastab injection (accessed 16 January 2010).

# Prochlorperazine (chlormeprazine, prochlorpemazine)

#### 12.5 mg/mL solution in 1-mL ampoules

- Prochlorperazine mesilate is a phenothiazine antipsychotic with a wide range of actions. It is a
  dopamine inhibitor; it has antiemetic activity; it has muscle relaxant properties; and it inhibits the
  heat-regulating centre.
- · It is used in the treatment of nausea and vomiting and in schizophrenia and acute mania.
- · Doses below are expressed in terms of prochlorperazine mesilate.

# **Pre-treatment checks**

• Do not use in comatose states, CNS depression, and phaeochromocytoma.

- Caution in renal or hepatic impairment, Parkinson disease, hypothyroidism, cardiac failure, myasthenia gravis, prostate hypertrophy, history of narrow-angle glaucoma or agranulocytosis.
- Use with caution in patients with risk factors for stroke.
- · Concomitant treatment with other antipsychotics should be avoided.
- Monitor patients with epilepsy or a history of seizures closely because prochlorperazine may lower the seizure threshold.

#### Biochemical and other tests (not all are necessary in an emergency situation)

ECG - to rule out any risk factors

LFTs

Renal function: U, Cr, CrCl (or eGFR) – start with small doses in severe renal impairment as increased cerebral sensitivity

# Dose

**Nausea and vomiting:** 12.5 mg by deep IM injection followed by oral medication 6 hours later if required.

**Schizophrenia and other psychotic disorders:** 12.5–25 mg two or three times a day by deep IM injection until oral treatment can be initiated.

Dose in renal impairment: reduce dose if CrCl <10 mL/minute.

Dose in hepatic impairment: reduce dose or avoid.

# Intramuscular injection

See Special handling below.

#### Preparation and administration

1. Withdraw the required dose.

Blood pressure

2. Give by deep IM injection into a large muscle such as the gluteal muscle.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Reference

1. Personal communiqué from Sanofi Aventis, 09 June 20009.

# Bibliography

SPC Stemetil (accessed 11 July 2008).

# Procyclidine hydrochloride

## 5 mg/mL solution in 2-mL ampoules

- Procyclidine hydrochloride is an antimuscarinic drug.
- It is used parenterally to treat drug-induced acute dystonic reactions and extrapyramidal symptoms.

# **Pre-treatment checks**

- Avoid in individuals with untreated urinary retention, closed-angle glaucoma and GI obstruction.
- Caution in cardiovascular disease, *†BP*, psychotic disorders, prostatic hypertrophy and pyrexia.

#### Dose

**Standard dose:** 5–10 mg by IV or IM injection, repeated after 20 minutes if necessary. Maximum daily dose 20 mg. Use the lower end of the dosage range in elderly patients or those of low bodyweight. The IV route should be effective within 5–10 minutes; occasionally patients may require up to 30 minutes for full effect.

# Intravenous injection

## Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection.

## Intramuscular injection

- 1. Withdraw the required dose.
- 2. Give by IM injection.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# **Bibliography**

SPC Kemadrin injection (10 April 2007 version).

# Progesterone

#### 50 mg/mL oily solution in 1-mL and 2-mL ampoules

- · Progesterone is a natural hormone that acts on the endometrium.
- It may be given by IM injection to treat dysfunctional uterine bleeding.
- It is also licensed (but no longer recommended) for the maintenance of early pregnancy following recurrent miscarriages due to inadequate luteal phase, or following in-vitro fertilisation or gamete intrafallopian transfer.

# **Pre-treatment checks**

- Avoid in undiagnosed vaginal bleeding, missed or incomplete abortion, mammary or genital tract carcinoma, thrombophlebitis, cerebral haemorrhage, severe hepatic dysfunction.
- Caution in patients with conditions that might be affected by fluid retention, e.g. *†BP*, cardiac disease or with a history of depression, diabetes, mild-moderate hepatic impairment, acute intermittent porphyria, migraine or photosensitivity.
- Progesterone may \glucose tolerance and patients with diabetes should be closely monitored.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure LFTs

## Dose

**Dysfunctional uterine bleeding:** 5–10 mg daily by IM injection for 5–10 days until 2 days before anticipated onset of menstruation.

# Intramuscular injection

- 1. Withdraw the required dose.
- 2. Give by deep IM injection into the buttock.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Gestone (accessed 29 September 2009).

# **Promethazine hydrochloride**

### 25 mg/mL solution in 1-mL and 2-mL ampoules

- Promethazine hydrochloride is a phenothiazine derivative. It acts as a sedating antihistamine with significant sedative, antimuscarinic, and some serotonin-antagonist properties.
- It is used for the symptomatic treatment of allergic conditions of the upper respiratory tract and skin including allergic rhinitis, urticaria and anaphylactic reactions to drugs and foreign proteins.
- It may be given IV as an adjunct in the emergency treatment of anaphylactic shock.
- It may also be used pre- and postoperatively in surgery and obstetrics for its sedative effects and for the relief of apprehension; it is often given with pethidine hydrochloride.

# **Pre-treatment checks**

- Avoid in patients taking monoamine oxidase inhibitors up to 14 days previously because of *†risk* of extrapyramidal side-effects.
- Use with caution in asthma, bronchitis or bronchiectasis as it may thicken secretions.
- Use with care in narrow-angle glaucoma, prostatic hypertrophy, urinary retention and pyloroduodenal obstruction because of its antimuscarinic effects.
- Use with care in epilepsy as it may lower the convulsive threshold.
- Promethazine is thought to be safe in acute porphyria.

Biochemical and other tests (not all are necessary in an emergency situation)

LFTs

# Dose

**Standard dose:** 25–50 mg by deep IM injection. If used for pre-medication, give 1 hour prior to surgery.

Adjunctive treatment of anaphylactic shock: 25–50 mg by slow IV injection (maximum 100 mg).

**Dose in hepatic impairment:** avoid in severe liver disease, may precipitate coma and is hepatotoxic.

# Intramuscular injection (preferred route)

Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by deep IM injection. Take care to avoid inadvertent SC injection (can cause local necrosis).

# Intravenous injection

- 1. Withdraw the required dose and dilute each 1 mL of injection to 10 mL with WFI.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV injection at a maximum rate of 25 mg/minute.
- 4. Take care to avoid extravasation or inadvertent intra-arterial injection (can cause necrosis and peripheral gangrene). If a patient complains of pain during IV injection, stop immediately.

# **Bibliography**

SPC Phenergan (accessed 24 January 2009).

# **Propranolol hydrochloride**

#### 1 mg/mL solution in 1-mL ampoules

- · Propranolol hydrochloride is a non-cardioselective beta-adrenoceptor blocker.
- · It is used IV for the emergency treatment of cardiac dysrhythmias and thyrotoxic crisis.

# **Pre-treatment checks**

- Treatment should be avoided in sick sinus syndrome, \BP, heart block greater than first degree, \pulse (<45-50 bpm), cardiogenic shock, overt heart failure and asthma.</li>
- · Caution in patients with a history of wheezing or peripheral circulatory conditions.
- · Caution in elderly patients or those of low bodyweight.

# Dose

**Standard dose:** 1 mg by IV injection which may be repeated at 2-minute intervals if necessary until a response is observed, or to a maximum dose of 10 mg in conscious patients or 5 mg in patients under anaesthesia.

# Intravenous injection

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 1 minute.

# Bibliography

SPC Inderal injection (accessed 17 September 2009).

# Protamine sulfate (protamine sulphate)

## 10 mg/mL solution in 5-mL and 10-mL ampoules

- Protamine sulfate is composed of a mixture of the sulfates of basic peptides prepared from the sperm or mature testes of suitable species of fish, usually *Clupeidae* or *Salmonidae*.
- It combines with heparin to form a stable inactive complex. It can therefore be used to treat
  haemorrhage resulting from severe heparin overdosage, both for unfractionated heparins (UFH)
  or low-molecular-weight heparins (LMWH).

# **Pre-treatment checks**

- Use with caution in patients with known sensitivity to fish, in vasectomised or infertile males, and in patients who have received previous protamine sulfate therapy or protamine insulin due to *\risk* of allergic reactions (see Counselling).
- Identification of type of heparin, route used and dose given.

#### Biochemical and other tests (not all are necessary in an emergency situation)

#### APTT or ACT

#### Dose

Dose is dependent on the amount and type of heparin to be neutralised, route of administration and the time that has elapsed since it was last given (heparin is continuously being excreted). Excessive doses of protamine sulfate can have an anticoagulant effect.

# 720 | Protamine sulfate

Protamine sulfate 1 mg can be expected to inhibit the effects of:

- Heparin (mucous) 100 units (UFH)
- Heparin (lung) 80 units (UFH)
- Bemiparin sodium 71 units (LMWH), i.e. 1.4 mg protamine sulfate for every 100 units
- Dalteparin sodium 100 units (LMWH)
- Enoxaparin sodium 1 mg (LMWH)
- Tinzaparin sodium 100 units (LMWH)

**Neutralisation of UFH given by IV injection:** by slow IV injection give 1 mg protamine sulfate for each 100 units of heparin (mucous) up to a maximum of 50 mg. Reduce the dose if more than 15 minutes have elapsed since IV injection of heparin; e.g. if 30–60 minutes have elapsed give 0.5–0.75 mg/100 units; if 2 hours or more have elapsed give 0.25–0.375 mg/100 units.

**Neutralisation of UFH given by IV infusion:** stop the infusion and give 25–50 mg protamine sulfate by slow IV injection. Maximum dose is 50 mg.

**Neutralisation of UFH given by SC injection:** give a total dose of 1 mg/100 units of heparin (mucous) as follows: initially with 25–50 mg by slow IV injection, then the remainder by IV infusion over 8–16 hours. Total maximum dose is 50 mg.

**Neutralisation of LMWH:** according to the dose equivalents stated above, give the required dose (up to a maximum of 50 mg) as an intermittent or continuous IV infusion. The anti-Factor Xa activity of LMWHs may not be completely reversed by protamine and may persist for up to 24 hours after administration.

# Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over about 10 minutes at a maximum rate of 5 mg/minute.

# Intermittent or continuous intravenous infusion

- 1. Withdraw the required dose and add to a convenient volume of NaCl 0.9% or Gluc 5%. Mix well.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion via a volumetric infusion device. Rate depends on indication.

# Protirelin (thyrotrophin-releasing hormone, TRH, TRF)

#### 100 micrograms/mL solution in 2-mL ampoules

- Protirelin is a hypothalamic releasing hormone that stimulates the release of thyrotrophin (thyroid-stimulating hormone, TSH) from the anterior pituitary.
- It is licensed for the diagnosis of mild hyperthyroidism or hypothyroidism, but its use has been largely superseded by immunoassays for TSH.
- It may be used to assess hypothalamic and pituitary function and TSH reserve by the interpretation of the various thyroid hormone levels pre and post dose.

# **Pre-treatment checks**

- Protirelin may have an effect on smooth muscle; closely monitor patients with asthma or other types of obstructive airways disease.
- Give cautiously to patients with myocardial ischaemia and severe hypopituitarism.

## Biochemical and other tests

Thyroid function: baseline TSH assay (and other thyroid hormones if appropriate) immediately prior to dose

#### Dose

Standard adult dose: 200 micrograms.

# Intravenous injection

- 1. Take blood sample immediately prior to the dose.
- 2. Withdraw the required dose.
- 3. Give by IV injection over 30 seconds.
- 4. Take a blood sample exactly 20 minutes after the injection for peak thyroid hormone assay and, if necessary, a further sample at exactly 60 minutes after injection to detect a delayed thyroid hormone response.

| Additional information                    |                                                                                                                                                                                                                                                                                                                                                                                                                             |                                                                                                                                           |
| Common and serious<br>undesirable effects | Following rapid IV injection most side-effects are mild and transient: nausea, desire to micturate, flushing, slight dizziness, peculiar taste, $\uparrow$ or $\downarrow$ BP, $\uparrow$ pulse. Protirelin also has prolactin-releasing activity and may cause breast enlargement and milk leakage in breast-feeding women.                                                                                                |                                                                                                                                           |
| Pharmacokinetics                          | TSH disappears rapidly from the plasma after IV injection. Over 90% is removed within 20 minutes with a half-life of about 5.3 minutes. About 5.5% of the dose is excreted in the urine, mostly within 30 minutes.                                                                                                                                                                                                          |                                                                                                                                           |

# Bibliography

SPC Protirelin ampoules (Cambridge Laboratories), Alliance Pharmaceuticals (accessed 9 February 2009).

# **Quinine dihydrochloride**

#### 300 mg/mL solution in 1-mL and 2-mL ampoules

- Quinine is an alkaloid originally obtained from the bark of the cinchona tree. It is the levorotatory isomer of quinidine.
- Quinine dihydrochloride (unlicensed product) is given by slow IV infusion in the treatment of falciparum malaria if the patient is seriously ill or unable to take oral therapy.
- Quinine doses are expressed as the salt; the dihydrochloride and sulphate (but not the bisulphate) contain about the same amounts of quinine base.

# **Pre-treatment checks**

- Do not give if there is known hypersensitivity to quinine, quinidine or mefloquine.
- Contraindicated in haemoglobinuria, myasthenia gravis, optic neuritis, tinnitus and in patients with a prolonged QT interval.
- Caution in cardiac disease (including atrial fibrillation, conduction defects, heart block) and G6PD deficiency.
- Omit the loading dose if the patient has received quinine or mefloquine during the previous 24 hours.

## Biochemical and other tests

| Blood glucose concentration | FBC                                          |
|-----------------------------|----------------------------------------------|
| Blood pressure              | LFTs (accumulation may occur with hepatitis) |
| Bodyweight                  | Pulse                                        |
| Electrolytes: serum Na, K   | Renal function: U, Cr, CrCl (or eGFR)        |

# Dose

Quinine should not be given by direct IV injection as this is now considered too hazardous.

#### WHO recommended regimen for severe or complicated falciparum malaria

**Initial loading dose:** 20 mg/kg (up to a maximum of 1.4 g) with maintenance infusions starting 8 hours after the start of the first infusion. Higher doses have been given in the critical care environment. A loading dose should **not be given** if the patient has received quinine or mefloquine during the previous 24 hours.

**Maintenance dose:** 10 mg/kg (up to a maximum of 700 mg) by IV infusion every 8 hours. If parenteral therapy is required for more than 48 hours, the maintenance dose should be reduced to 5–7 mg/kg. A switch to oral therapy should be made as soon as possible.

Dose in renal impairment: adjusted according to creatinine clearance:<sup>1</sup>

- CrCl >20-50 mL/minute: 5-7 mg/kg every 8 hours.
- CrCl 10-20 mL/minute: 5-7 mg/kg every 8-12 hours.
- CrCl <10 mL/minute: 5–7 mg/kg every 24 hours.</li>

# Intravenous infusion (preferred route)

- 1. Withdraw the required dose and add to 250 mL NaCl 0.9% or Gluc 5%.
- The solution should be clear and colourless to very pale straw in colour. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV infusion over 4 hours via a volumetric infusion device, taking care to avoid extravasation.

# Intramuscular injection (very irritant, use only if no alternative – efficacy not proven; dose as IV)

# Preparation and administration

- 1. Withdraw half the required dose and further dilute with NaCl 0.9% to give a solution containing 60-100 mg/mL (i.e. dilute each 1 mL to 3-5 mL).
- 2. Withdraw the other half of the dose and dilute in the same way.
- 3. Give each half dose by IM injection into the anterior thigh (not the buttock). Rotate injection sites for subsequent injections.

# Quinupristin with dalfopristin

#### 500-mg dry powder vials

- Quinupristin and dalfopristin (both as mesilate salts) are semi-synthetic streptogramin antibacterials and are used in the ratio 3:7. They each have bacteriostatic activity and in combination usually act synergistically to produce bactericidal activity.
- The combination is used against a range of Gram-positive and some Gram-negative organisms, but
  is reserved for the treatment of serious infections with multidrug-resistant Gram-positive bacteria,
  such as MRSA and vancomycin-resistant *Enterococcus faecium*.
- Quinupristin with dalfopristin doses are expressed as the combined mass (mg) of the two constituents:

Quinupristin with dalfopristin  $500 \text{ mg} \equiv \text{quinupristin } 150 \text{ mg}$  with dalfopristin 350 mg.

# **Pre-treatment checks**

- Do not give if there is known hypersensitivity to quinupristin, dalfopristin, or other streptogramins.
- Caution if predisposed to cardiac arrhythmias (including congenital QT syndrome, concomitant use
  of drugs that prolong QT interval, cardiac hypertrophy, dilated cardiomyopathy, \L, \Mg, \pulse).

#### Biochemical and other tests (not all are necessary in an emergency situation)

Bodyweight LFTs

# Dose

**Standard dose:** 7.5 mg/kg every 8 hours for 7 days in skin and soft-tissue infections; for 10 days in hospital-acquired pneumonia; duration of treatment in *E. faecium* infection is dependent on clinical response. The product is licensed for 12-hourly dosing for skin and soft-tissue infections.

**Dose in hepatic impairment:** 5 mg/kg (if 7.5 mg/kg is not tolerated) in moderate hepatic impairment. Avoid in severe hepatic impairment. Do not use if plasma bilirubin is >3 times ULN.

# Intermittent intravenous infusion

Preparation and administration

Give via central venous catheter.

In an emergency the first dose may be diluted in 250 mL Gluc 5% and given over 60 minutes via a peripheral line, but this is very likely to cause venous irritation. Quinupristin with dalfopristin is incompatible with NaCl 0.9%.

- 1. Reconstitute each 500-mg vial with 5 mL WFI or Gluc 5%, gently swirling vial without shaking to dissolve the powder, to give a solution containing 100 mg/mL.
- 2. Allow to stand for at least 2 minutes until foam disappears and the solution is clear.
- 3. Within 30 minutes of reconstitution withdraw the required dose and add to 100 mL Gluc 5%.
- The solution should be clear and colourless to yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Flush the line with Gluc 5% before commencing infusion.
- 6. Give by IV infusion over 60 minutes via a central venous catheter.
- 7. Flush the line again with Gluc 5% at the end of the infusion.

# 728 | Quinupristin with dalfopristin

| Technical information       |                                                                                                                                                                                                                                                                              |  |  |

# Bibliography

SPC Synercid IV (accessed 2 April 2009).

# Ranitidine

#### 25 mg/mL solution in 2-mL ampoules

- Ranitidine hydrochloride is a histamine H<sub>2</sub>-receptor antagonist that rapidly inhibits both basal and stimulated gastric acid secretion and reduces pepsin output.
- It is used where inhibition of gastric acid secretion may be beneficial: the treatment of duodenal and benign gastric ulceration, stress ulceration, pathological hypersecretory states such as the Zollinger-Ellison syndrome and in patients at risk of acid aspiration during general anaesthesia or childbirth.
- Doses are expressed in terms of the base: Ranitidine 50 mg ≈ 56 mg of ranitidine hydrochloride.

# **Pre-treatment checks**

- · Avoid in patients with a history of porphyria.
- H<sub>2</sub>-receptor antagonists may mask symptoms of gastric cancer and particular care is required in those whose symptoms change and in those who are middle-aged or older.

#### Biochemical and other tests

Bodyweight Renal function: U, Cr, CrCl (or eGFR)

# Dose

Standard dose: 50 mg by IV injection, IV infusion or IM injection, repeated every 6-8 hours if necessary.

**Continuous infusion:** for the prophylaxis of upper GI haemorrhage from stress ulceration in seriously ill patients, initially 50 mg by IV injection followed by 125–250 micrograms/kg/hour by IV infusion.

**Patients at risk of acid aspiration:** 50 mg by IV or IM injection 45–60 minutes before induction of general anaesthesia.

Dose in renal impairment: adjusted according to creatinine clearance:

- CrCl >50 mL/minute: dose as in normal renal function.
- CrCl < 50 mL/minute: reduce individual doses to 25 mg.

# Intramuscular injection

## Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by deep IM injection into a large muscle such as the gluteus or lateral aspect of the thigh.

# Intravenous injection

## Preparation and administration

- 1. Withdraw the required dose and dilute to 20 mL with NaCl 0.9%.
- 2. Give by IV injection over 2–5 minutes.

# Intermittent intravenous infusion

- 1. Withdraw the required dose and add to a suitable volume of compatible infusion fluid (e.g. 100 mL NaCl 0.9%).
- 2. Give by IV infusion at a rate of 25 mg/hour.

# **Continuous intravenous infusion**

# Preparation and administration

- 1. Withdraw the required dose and add to a suitable volume of compatible infusion fluid. Mix well.
- 2. Give by IV infusion at a rate of 125–250 micrograms/kg/hour.

# Bibliography

SPC Ranitidine 50 mg/2 mL solution for injection and infusion, Beacon Pharmaceuticals (accessed 28 March 2010).

# Rasburicase

# 1.5-mg and 7.5-mg dry powder vials with solvent

- · Rasburicase is a recombinant form of urate oxidase.
- It is used in the treatment and prophylaxis of acute hyperuricaemia, in order to prevent acute renal failure, in patients with haematological malignancy at risk of rapid tumour lysis at the start of chemotherapy.

# **Pre-treatment checks**

Do not administer to patients with G6PD or other cellular metabolic disorders known to cause haemolytic anaemia.

#### Biochemical and other tests

Bodyweight

# Dose

Standard dose: 200 micrograms/kg/day for up to 7 days depending upon plasma uric acid levels and clinical judgement.

# Intermittent intravenous infusion

- 1. Reconstitute each 1.5-mg vial with 1 mL supplied solvent (use 5 mL for each 7.5-mg vial). Swirl very gently (do not shake) to give a solution containing 1.5 mg/mL.
- 2. Withdraw the required dose (more than one vial may be required) and add to 50 mL NaCl 0.9%.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 30 minutes through a different line to that used for chemotherapy treatment. If this is not possible, flush the line with at least 15 mL of NaCl 0.9% before and after the rasburicase infusion. Do not use a filter for the infusion.

# Bibliography

SPC Fasturtec (accessed 26 November 2008).

# Reteplase

#### 10-units dry powder vials with 10 mL WFI in pre-filled syringe

- Reteplase is a recombinant plasminogen activator with some fibrin specificity. It has thrombolytic activity.
- · It is licensed for the dissolution of clots in STEMI.
- Reteplase doses are expressed in units specific to reteplase that are not directly comparable with units of other thrombolytic agents.

# **Pre-treatment checks**

Contraindicated in recent haemorrhage, trauma, or surgery (including dental extraction), coagulation defects, bleeding diatheses, aortic dissection, aneurysm, coma, history of cerebrovascular disease especially recent events or with any residual disability, recent symptoms of possible peptic ulceration, heavy vaginal bleeding, severe *†BP*, active pulmonary disease with cavitation, acute pancreatitis, pericarditis, bacterial endocarditis, severe liver disease, and oesophageal varices.

- Do not use in ↓glycaemia, ↑glycaemia.
- Use with caution if there is a risk of bleeding including that from venepuncture or invasive procedures.
- Caution in external chest compression, pregnancy, elderly patients, <sup>†</sup>BP, conditions in which thrombolysis might give rise to embolic complications such as enlarged left atrium with atrial fibrillation (risk of dissolution of clot and subsequent embolisation), and recent or concurrent use of drugs that <sup>†</sup>risk of bleeding.
- · Heparin and aspirin should be administered before and after reteplase to reduce the risk of re-thrombosis.

LFTs

#### Biochemical and other tests (not all are necessary in an emergency situation)

APTT ratio if heparin is to be used Blood pressure and pulse – do not give if systolic BP >160

## Dose

Acute MI (initiated within 12 hours of onset of symptoms): 10 units by IV injection as soon as possible after the onset of symptoms. Repeat the dose once after 30 minutes.

**Concomitant therapy with aspirin:** 300 mg prior to thrombolysis, followed by 75–150 mg once daily at least until discharge.

**Concomitant therapy with unfractionated heparin:** 5000 units given by IV injection prior to reteplase therapy followed by an infusion of 1000 units/hour starting after the second reteplase dose. Heparin should be given for at least 24 hours, preferably for 48–72 hours with the aim of keeping APTT ratio at 1.5–2.

**Central venous catheter occlusion (unlicensed):** a dose of 0.4 units has been used, repeated after 2 hours if necessary. See below for administration method.

Dose in renal impairment: use with caution if CrCl <10 mL/minute.

Dose in hepatic impairment: do not give in severe disease.

#### Intravenous injection

#### Preparation

- 1. Remove the protective flip-cap from the vial and clean the rubber closure with an alcohol wipe.
- 2. Open the package containing the reconstitution spike; remove both protective caps from this.
- 3. Insert the spike through the rubber closure into the vial of reteplase.
- 4. Take the 10-mL syringe out of the package. Remove the tip cap from the syringe. Connect the syringe to the reconstitution spike and transfer the  $10 \,\text{mL}$  of solvent into the vial.
- 5. With the reconstitution spike and syringe still attached to the vial, swirl the vial gently to dissolve the injection powder. Do not shake.
- 6. Withdraw 10 mL of the solution back into the syringe. A small amount of solution may remain in the vial owing to overfill. Disconnect the syringe from the reconstitution spike.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

- 1. Check the compatibility of the syringe with the IV access device. If necessary an adaptor may be used.
- 2. Give by slow IV injection over a maximum of 2 minutes.

# **Catheter lock (unlicensed)**

- 1. Prepare as steps 1-5 above.
- 2. Withdraw 0.4 mL into a second empty syringe and dilute to the catheter volume with WFI.
- 3. Aspirate the catheter.
- 4. Inject the reteplase solution into the catheter.
- 5. Allow to dwell for at least 30 minutes, then aspirate.

# Bibliography

SPC Rapilysin 10U (accessed 31 March 2010).

# Rifampicin (rifampin)

#### 600-mg dry powder vials with solvent

- · Rifampicin belongs to the rifamycin group of antimycobacterials.
- It is used in the treatment of various infections due to mycobacteria and other susceptible organisms and is usually given with other antibacterials to prevent the emergence of resistant organisms.
- Rifampicin is well absorbed from the GI tract following oral dosing, so the IV route should be used only when the oral route is unavailable.

#### **Pre-treatment checks**

- · Do not give if there is known hypersensitivity to rifamycins or in jaundice.
- · Contraindicated if given concomitantly with saquinavir/ritonavir combination.
- · Caution in acute porphyria, pregnancy and breast feeding.

#### Biochemical and other tests

Bodyweight Electrolytes: serum Na, K FBC LFTs Renal function: U, Cr Sputum cultures and chest X-ray if tuberculosis suspected U&Es

#### Dose

Rifampicin must not be given by the IM or SC route (local irritation and inflammation can occur).

Tuberculosis: 600 mg daily in combination with other antibacterials.

**Brucellosis, Legionnaires' disease, endocarditis and serious staphylococcal infections:** 300–600 mg every 12 hours in combination with other antibacterials (may also be given as 150–300 mg every 6 hours).

**Multibacillary leprosy:** 600 mg monthly for adults (or 450 mg if <35 kg) in combination with clofazimine and dapsone. Treatment is continued for 12 months.
**Paucibacillary leprosy:** 600 mg monthly for adults (or 450 mg if <35 kg) in combination with dapsone. Treatment is continued for 6 months.

Dose in hepatic impairment: the total daily dose should not exceed 8 mg/kg.

#### Intermittent intravenous infusion

#### Preparation and administration

- 1. Reconstitute each 600-mg vial with the solvent provided. Swirl gently until fully dissolved to give a solution containing 60 mg/mL.
- 2. Withdraw the required dose and add to 500 mL Gluc 5% (preferred) or other compatible infusion fluid.
- 3. The solution should be clear and red to reddish brown in colour. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV infusion over 2–3 hours taking care to avoid extravasation. If local irritation or inflammation occurs at the infusion site, the infusion should be discontinued and restarted at another site.

**Fluid restriction (unlicensed):** 300–600 mg may be added to 100 mL Gluc 5% (preferred) or NaCl 0.9% and given by IV infusion over 2–3 hours.

## Bibliography

SPC Rifadin for infusion 600 mg (accessed 2 April 2009).

# **Risperidone long-acting injection**

#### 25-mg, 37.5-mg and 50-mg dry powder vials with solvent

- Risperidone is a benzisoxazole atypical antipsychotic, reported to be an antagonist at dopamine, serotonin, adrenergic, and histamine receptors.
- As a long-acting depot injection it is used in the maintenance treatment of schizophrenia in patients already stabilised on oral antipsychotics.

#### Pre-treatment checks

Patients with no history of risperidone use should be given oral risperidone for several days to assess tolerability.

#### Biochemical and other tests

| Blood pressure | LFTs           |
|----------------|----------------|
| Bodyweight     | Prolactin      |
| ECG            | Renal function |

#### Dose

After administration, initially <1% risperidone will be released, followed by a lag time of 3 weeks before the main release of risperidone occurs. When initiating treatment with risperidone depot injection, oral risperidone (or the patient's previous antipsychotic if not risperidone) should also be provided for the first 3 weeks after the first injection.

Patients not stabilised on risperidone or patients stabilised on up to 4 mg oral risperidone daily for at least 2 weeks: initiate therapy at 25 mg by IM injection every 2 weeks. Patients stabilised more than 4 mg oral risperidone daily for at least 2 weeks: initiate therapy at 37.5 mg by IM injection every 2 weeks.

**Maintenance therapy:** increase the dose if necessary at intervals of at least 4 weeks in steps of 12.5 mg up to a maximum of 50 mg every 2 weeks.

## Intramuscular injection

#### Preparation and administration

- 1. The pack should be removed from the refrigerator and allowed to come to room temperature before reconstitution.
- 2. Follow the manufacturer's instructions to reconstitute the vial with the diluent provided to give a thick, milky suspension containing 25 mg/2 mL, 37.5 mg/2 mL or 50 mg/2 mL depending on vial size.
- 3. The entire contents of the suspension in the vial should be drawn up.
- 4. Shake the syringe vigorously to re-suspend the microspheres and give the dose by deep IM injection into the gluteal or deltoid muscle. For gluteal administration use a 50-mm needle and alternate injections between the buttocks; for deltoid administration use a 25-mm needle and alternate between the arms

# **Rituximab**

#### 10 mg/mL solution in 10-mL and 50-mL vials

- Rituximab is a genetically engineered chimeric monoclonal antibody that binds specifically to the CD20 antigen.
- It is used with methotrexate in adults with severe active rheumatoid arthritis who have had an inadequate response to DMARDs including anti-TNF agents.
- It is also licensed for use in non-Hodgkin lymphoma and chronic lymphocytic leukaemia (see specialist literature for dosing details).

#### **Pre-treatment checks**

- Caution in patients with a history of cardiovascular disease because exacerbation of angina, arrhythmia, and heart failure have been reported.
- · Patients should be premedicated with paracetamol (acetaminophen) and an antihistamine.
- Screen for the presence of active or severe infection; screen for hepatitis B virus (HBV) in high-risk
  patients.
- Ensure full resuscitation facilities are immediately available throughout the administration period.

#### Biochemical and other tests

Blood pressure FBC Possibly bodyweight and height

#### Dose

Rheumatoid arthritis: 1 g by IV infusion followed 2 weeks later by a second dose of 1 g.

- Give methylprednisolone 100 mg by IV injection 30 minutes prior to rituximab to ↓severity of acute infusion reactions.
- If a repeat course of treatment is considered, it should be given after a minimum interval of 16 weeks.

#### Intravenous infusion through a dedicated line

#### Preparation and administration

Preparation should take place in a CIVAS unit. Administer only in an environment where full resuscitation facilities are immediately available.

- 1. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 2. Give by IV infusion.
  - For the first infusion: initially administer at 50 mg/hour increased in 50 mg/hour increments every 30 minutes to a maximum of 400 mg/hour.
  - For subsequent infusions: initially administer at 100 mg/hour increased in 100 mg/hour increments at 30-minute intervals to a maximum of 400 mg/hour.

#### 744 | Rituximab

# **Bibliography**

SPC Mabthera 100 mg and 500 mg concentrate for solution for infusion (accessed 4 March 2010).

# Salbutamol (albuterol)

#### 500 micrograms/mL solution in 1-mL ampoules; 1 mg/mL solution in 5-mL ampoules

- Salbutamol sulfate is a direct-acting sympathomimetic with mainly beta-adrenergic activity and a selective action on beta<sub>2</sub> receptors.
- It can be given by various parenteral routes in the management of severe bronchospasm and by IV
  infusion to delay uncomplicated premature labour.
- It has been used (unlicensed) to treat ↑K but this use is controversial.
- Doses are expressed in terms of the base: Salbutamol 1 mg ≈ 1.2 mg salbutamol sulfate.

#### **Pre-treatment checks**

- Avoid use in patients with underlying severe heart disease, e.g. ischaemic heart disease, arrhythmia
  or severe heart failure.
- · Use with caution in thyrotoxicosis.
- In asthma, use should be combined with oxygen and corticosteroid therapy.
- · Hypoglycaemic therapy in diabetes may require review.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Blood glucose                                  | Bodyweight                                 |
|------------------------------------------------|--------------------------------------------|
| Blood pressure and pulse (in the USA an ECG is | Electrolytes: serum K                      |
| sometimes performed in addition)               | Respiratory function: ABGs, pulse oximetry |

#### Dose

#### Severe bronchospasm:

- By IV infusion, initially 5 micrograms/minute, adjusted according to response and heart rate; usually in range 3–20 micrograms/minute, or more if necessary.
- Alternatively, give 250 micrograms (4 micrograms/kg) by slow IV injection (repeated if necessary) or 500 micrograms (8 micrograms/kg bodyweight) by SC or IM injection repeated every 4 hours as required.

**Premature labour:** glucose is the preferred diluent and use of a syringe pump is the preferred means of administration (*†*risk of maternal pulmonary oedema if saline or large volumes of fluid are used).

- Initially 10 micrograms/minute given by IV infusion, increasing the rate at 10-minute intervals until there is diminution in strength, frequency or duration of contractions.
- The infusion rate may then be increased slowly until contractions cease.
- The infusion is maintained at this level for one hour and then gradually decreased over several hours.
- Infusion rates providing 10–45 micrograms/minute are generally adequate to control uterine contractions.
- After stopping the infusion, treatment may be continued by giving salbutamol 4 mg orally 3–4 times daily, bearing in mind that risk to the mother increases after 48 hours of treatment.

**Hyperkalaemia (unlicensed):** 500 micrograms by slow IV injection has been used, repeated after 2 hours if necessary. However, this use is controversial as it is reportedly no more effective than 10–20 mg nebulised salbutamol and may be more likely to cause cardiac arrhythmias. If effective,  $\downarrow K$  levels are seen in 30 minutes and the effect may last for up to 2 hours.<sup>1</sup>

## Continuous intravenous infusion via a syringe pump

#### Preparation of a 200 micrograms/mL solution

- 1. Using the 5 mg/5 mL strength, withdraw 10 mg (10 mL).
- Make up to 50 mL in a syringe pump with NaCl 0.9% or Gluc 5% (Gluc 5% is the preferred diluent in premature labour).
- 3. Cap the syringe and mix well to give a solution containing 200 micrograms/mL.
- The solution should be clear and colourless or faintly straw-coloured. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

Give by IV infusion at the required rate, adjusting the dose according to response and heart rate.

## Continuous intravenous infusion (large volume infusion)

#### Preparation of a 20 micrograms/mL solution

- 1. Withdraw 10 mL from a 500-mL bag of NaCl 0.9% or Gluc 5% and discard.
- 2. Using the 5 mg/5 mL strength of salbutamol, withdraw 10 mg (10 mL) and add to the prepared infusion bag to give a solution containing 20 micrograms/mL. Mix well.
- The solution should be clear and colourless or faintly straw-coloured. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

Give by IV infusion at the required rate via a volumetric infusion device, adjusting the dose according to response and heart rate.

#### Intravenous injection

#### Preparation and administration

- 1. Using the 500 micrograms/mL strength, withdraw 250 micrograms (0.5 mL).
- 2. Dilute to 5 mL with WFI to give a solution containing 50 micrograms/mL.
- 3. The solution should be clear and colourless or faintly straw-coloured. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by slow IV injection over 3-5 minutes.

#### **Subcutaneous injection**

#### Preparation and administration

- 1. Using the 500 micrograms/mL strength, withdraw the required dose.
- 2. Give by SC injection.

#### Intramuscular injection

#### Preparation and administration

- 1. Using the 500 micrograms/mL strength, withdraw the required dose.
- 2. Give by IM injection.

# **Selenium**

#### 50 micrograms/mL solution in 2-mL and 10-mL ampoules

- Selenium is an essential trace element that acts as a co-factor in various enzymes in the human body.
- Sodium selenite pentahydrate injection is used when there is proven selenium deficiency that cannot be remedied from food sources.
- Doses are expressed as selenium: Selenium 100 micrograms ≡ 333 micrograms sodium selenite pentahydrate.

## **Pre-treatment checks**

Avoid in selenosis.

#### Dose

**Standard dose:** 100–200 micrograms daily by IM or IV injection increased to a maximum of 500 micrograms daily if required.

Dose in renal and hepatic impairment: no information available.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection.

#### Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Selenase solution for injection (50 micrograms/mL) (accessed 30 September 2009).

# Sodium aurothiomalate

20 mg/mL solution in 0.5-mL (10-mg) ampoules; 100 mg/mL solution in 0.5-mL (50-mg) ampoules

Sodium aurothiomalate should be used under specialist supervision only.

- · Sodium aurothiomalate is gold-containing compound with anti-inflammatory activity.
- It is used as a DMARD in the management of active progressive rheumatoid arthritis and juvenile idiopathic arthritis.

#### **Pre-treatment checks**

Do not use in pregnancy, or severe renal or hepatic disease, a history of blood disorders, exfoliative dermatitis, systemic lupus erythematosus, necrotising enterocolitis, pulmonary fibrosis or porphyria.

#### Biochemical and other tests

Follow any local guidelines. FBC LFTs Pulmonary function Renal function: U, Cr

Signs of abnormal bruising or severe sore throat Skin examination Urinalysis

#### Dose

Test dose: 10 mg by IM injection in first week to assess tolerability.

**Maintenance dose**: after the test dose give 50 mg weekly by IM injection until there is evidence of remission. Benefit is not expected until 300–500 mg has been given. The dose frequency may then be reduced to every 2 weeks until full remission occurs and then further reduced on specialist advice. If there is no evidence of improvement after a total dose of 1 g has been given, and if there are no signs of gold toxicity, then 100 mg may be given every week for 6 weeks. Discontinue if there is no evidence of remission.

#### Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Inspect visually and do not use if the solution has darkened (i.e. more than pale yellow).
- 3. The patient should be lying down.
- 4. Give by deep IM injection preferably into the gluteal muscle. Gently massage the area after administration. Rotate injection sites for subsequent injections.

## Bibliography

SPC Myocrisin (accessed 2 December 2008).

# Sodium bicarbonate

#### 1.26% solution in 500-mL and 1000-mL infusion containers

#### 4.2% solution in 10-mL pre-filled syringes and 500-mL infusion containers

#### 8.4% solution in 10-mL and 50-mL pre-filled syringes and 200-mL infusion containers

- Sodium bicarbonate is a buffer that breaks down to water and CO<sub>2</sub> after combining with hydrogen ions. It is reabsorbed by the kidney following glomerular filtration and this action is balanced by the excretion of hydrogen ions to maintain the systemic pH.
- Normal range for serum bicarbonate: 20–30 mmol/L.
- It is sometimes used IV to *†*serum bicarbonate, buffer excess hydrogen ion concentration and *†*blood pH, thus correcting metabolic acidosis.
- Sodium bicarbonate  $1 g \equiv 12 \text{ mmol of Na}$  and  $HCO_3$ .
- Table S1 shows the electrolyte content of different strengths and volumes of solution.

#### **Pre-treatment checks**

- Do not use in renal failure, metabolic or respiratory alkalosis, ↑BP, oedema, congestive heart failure, hypoventilation, a history of urinary calculi, and co-existent ↓K, ↓Ca, ↓Cl or ↑Na.
- Whenever respiratory acidosis is concomitant with metabolic acidosis, both pulmonary ventilation and perfusion must be adequately supported to remove excess CO<sub>2</sub>.
- Caution should also be used in patients receiving corticosteroids and in geriatric or postoperative patients.

 Table S1
 Electrolyte content of various strengths and volumes of sodium bicarbonate solutions

| Strength:             | 1 <b>.26</b> % | 1 <b>.26</b> % | <b>4.2</b> % | 4.2%   | <b>8.4</b> % | 8.4%  | 8.4%   |
|-----------------------|----------------|----------------|--------------|--------|--------------|-------|--------|
| Volume:               | 500 mL         | 1000 mL        | 10 mL        | 500 mL | 10 mL        | 50 mL | 200 mL |
| Sodium<br>(mmol)      | 75             | 150            | 5            | 250    | 10           | 50    | 200    |
| Bicarbonate<br>(mmol) | 75             | 150            | 5            | 250    | 10           | 50    | 200    |

#### Biochemical tests (not all are necessary in every situation)

| Acid-base balance                 | LFTs                                  |
|-----------------------------------|---------------------------------------|
| Electrolytes: serum Na, K, Ca, Cl | Renal function: U, Cr, CrCl (or eGFR) |

#### Dose

#### Correction of metabolic acidosis:

- *Mild metabolic acidosis associated with dehydration:* manage initially with appropriate fluid replacement. Acidosis usually improves as tissue and renal perfusion improve.
- Severe metabolic acidosis (pH <7.1): the advice of a senior doctor should be sought before proceeding
   <ul>
   use is controversial. An appropriate volume of sodium bicarbonate 1.26% may be given by IV infusion over 3–4 hours according to body base deficit. The rate may be increased in 'life-threatening' conditions, e.g. 50 mmol may be given over 1 hour in severe DKA. Plasma pH, electrolytes (particularly K) and pCO<sub>2</sub> must be closely monitored and over-correction avoided. Allow natural compensatory mechanisms to make the final approach to normal acid–base balance.

**Correction of acidosis during advanced cardiac life support:** routine use is not recommended. Give sodium bicarbonate 50 mmol (as 50 mL 8.4%) by IV injection if cardiac arrest is associated with  $\uparrow$ K or tricyclic antidepressant overdose. Repeat the dose according to the clinical condition of the patient and the results of repeated blood gas analysis.<sup>1</sup>

#### Intravenous injection

Preparation and administration

Concentrations >1.26% should be given via a central line except in emergencies. Sodium bicarbonate solution is incompatible with Hartmann's and Ringer's solutions.

- 1. Either assemble a pre-filled syringe according to the manufacturer's instructions or withdraw the required dose from an infusion container.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by slow IV injection. Concentrations >1.26% should be given via a central line (see Osmolarity below) except in emergency situations.

#### Intravenous infusion

Preparation and administration

Concentrations >1.26% should be given via a central line. Sodium bicarbonate solution is incompatible with Hartmann's and Ringer's solutions.

- 1. The infusion is pre-prepared for use. It should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV infusion via a volumetric infusion device at the required rate. Concentrations >1.26% should be given via a central line (see Osmolarity below) except in emergency situations.
- 3. Discard any unused portion. Do not reconnect partially used infusion containers.

# Sodium chloride

# 0.9% solution in ampoules, vials and infusion containers of various volumes 0.45%, 1.8%, 2.7% and 5% solution in 500-mL infusion containers

#### 30% solution in 10-mL ampoules

- Sodium is the major extracellular electrolyte and its role and metabolism are closely related to the body's water balance.
- Sodium chloride in water forms a crystalloid intravenous fluid. The 0.9% solution is commonly
  called normal saline or physiological saline because it is isotonic with plasma, but prescriptions
  should always specify strength as a percentage.

- Normal range for serum sodium: 135-145 mmol/L.
- NaCl 0.9% is used to replenish extracellular fluid and is also widely used as a vehicle or diluent for the administration of compatible parenteral drugs.
- NaCl 1.8% may sometimes be used cautiously to correct ↓Na; other strengths may be added to parenteral nutrition regimens to provide Na supplementation.
- NaCl 0.9% and NaCl 0.45% may also be given (unlicensed) by SC infusion (hypodermoclysis).
- Sodium chloride  $1 g \equiv 17.1 \text{ mmol of Na and Cl.}$
- Sodium chloride  $2.54 \text{ g} \equiv 1 \text{ g}$  sodium.
- Table S2 shows the electrolyte content of different strengths and volumes of solution.

#### **Pre-treatment checks**

- Caution in patients with *†BP*, heart failure, peripheral or pulmonary oedema, renal impairment, liver cirrhosis, pre-eclampsia, toxaemia of pregnancy or other conditions associated with Na retention.
- Caution should also be used in patients receiving corticosteroids and in elderly or postoperative patients.

#### Biochemical tests (not all are necessary in every situation)

Acid–base balance Electrolytes: serum Na, K

#### Dose

**Treatment or prevention of fluid depletion:** dose is dependent upon the age, weight, biochemistry and clinical condition of the patient. Normal fluid requirements are generally about 40 mL/kg/ 24 hours. The use of colloid solutions should be considered where plasma expansion is required due to ↑losses.

**Hyponatraemia:** therapy is guided by the rate of development and degree of  $\lfloor Na$ , accompanying symptoms, the state of water balance, and taking into account the underlying cause.

- Mild asymptomatic ↓Na: does not usually require specific therapy.
- Chronic mild to moderate 1Na due to, e.g. salt-losing bowel or renal disease: give oral NaCl supplements whilst ensuring adequate fluid intake.
- Chronic dilutional ↓Na, which is often asymptomatic, can be managed by correcting the underlying cause. Fluid restriction may be necessary, particularly in the short term, and drugs interfering with the action of ADH should be stopped if possible.
- Severe acute (or chronic) ↓Na may require the use of NaCl 0.9% by IV infusion (which is effectively hypertonic in these circumstances). In very severe ↓Na, cautious use of NaCl 1.8% may be necessary. The deficit should be corrected slowly to avoid the risk of osmotic demyelination syndrome:

#### 758 | Sodium chloride

rise in serum Na should be no more than 10 mmol/L in 24 hours. The aim is to render the patient asymptomatic (serum Na 120–130 mmol/L). Loop diuretics, e.g. furosemide are often also given, especially if fluid overload is likely to be a problem. Hypertonic solutions should be used with caution as over-rapid correction may have severe neurological adverse effects.

**Hypernatraemia:** hypernatraemia is usually due to water loss in excess of Na loss. Treatment should correct the underlying cause and usually involves water replacement: simply drinking water may be sufficient in some patients. In more severe conditions, Gluc 5% may be given by slow IV infusion. Alternatively, if volume depletion is severe, NaCl 0.9% may be given by IV infusion (as it is relatively hypotonic).

#### Intravenous infusion

#### Preparation and administration

- 1. The infusion is pre-prepared for use. It should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 2. Give by IV infusion at the required rate.
- 3. Discard any unused portion. Do not reconnect partially used infusion containers.

# Sodium fusidate (fusidate sodium)

#### 500-mg dry powder vials with buffered solvent

- · Sodium fusidate is a steroidal antibacterial with a bacteriostatic or bactericidal activity.
- It is used mainly against Gram-positive bacteria, particularly in susceptible staphylococcal infections. It is usually given in combination with other antibacterials to prevent the emergence of resistance.
- Doses are expressed in terms of sodium fusidate: Sodium fusidate  $500 \text{ mg} \equiv 480 \text{ mg}$  fusidic acid.

## **Pre-treatment checks**

#### Biochemical tests

Bodyweight FBC LFTs

#### Dose

Sodium fusidate must not be given by IM or SC injection as this causes local tissue necrosis.

Adults 50 kg or more: 500 mg three times daily.

Adults less than 50 kg: 6–7 mg/kg three times daily (equivalent to 6–7 mL/kg of the final infusion solution).

#### Intermittent intravenous infusion

Preparation and administration

Infusion via a central venous line is preferred (risk of vasospasm); if use of a peripheral line is essential use a large vein and infuse over a longer period (see below).

- 1. Reconstitute a 500-mg vial with 10 mL of the solvent provided and add the entire contents of the vial to 500 mL of compatible infusion fluid (usually NaCl 0.9%)
- 2. Mix well to give a solution containing approximately 1 mg/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present. If opalescence develops, the solution must be discarded.
- 4. Give by IV infusion via a central venous line (preferred) over at least 2 hours. If a peripheral vein is used (must be a wide-bore vein with a good blood flow), give by IV infusion over at least 6 hours as there is a risk of vasospasm, thrombophlebitis and haemolysis if it is given too rapidly.

# Bibliography

SPC Sodium Fusidate 500 mg for intravenous infusion, Leo Laboratories Ltd (accessed 2 April 2009).

# Sodium nitrite

#### 300 mg/10 mL solution in vials

- Sodium nitrite is used with sodium thiosulfate in the treatment of cyanide poisoning.
- Sodium nitrite produces methaemoglobinaemia and it is thought that cyanide ions combine with the methaemoglobin to produce cyanmethaemoglobin, thus protecting cytochrome oxidase from the cyanide ions; however, other mechanisms may have a significant role. As the cyanmethaemoglobin slowly dissociates, the cyanide is converted to relatively non-toxic thiocyanate and is excreted in the urine.
- Sodium thiosulfate provides an additional source of sulfur for this reaction and this accelerates the
  process.

# Pre-treatment checks

- Do not give sodium nitrite to asymptomatic patients who have been exposed to cyanide.
- Do not give sodium nitrite to symptomatic patients if dicobalt edetate is available.

#### 762 | Sodium nitrite

- It is important to be aware if any cyanide antidote therapy has been given in the pre-hospital setting as repeat doses of some antidotes can cause serious side-effects.
- Use with caution in patients with acquired or congenital methaemoglobinaemia, as sodium nitrite will exacerbate this condition.
- Patients with G6PD are theoretically at great risk from sodium nitrite therapy because of the likelihood of haemolysis, although no such cases have been reported.

## Doses of cyanide poisoning antidotes (see relevant entries)<sup>1</sup>

It is essential to consult a poisons information service, e.g. Toxbase at www.toxbase.org (password or registration required) for full details of the management of cyanide toxicity.

#### Mild poisoning (nausea, dizziness, drowsiness, hyperventilation, anxiety):

- Observe.
- Give 12.5 g sodium thiosulfate (50 mL of 25% or 25 mL of 50% solution) IV over 10 minutes.

# Moderate poisoning (reduced conscious level, vomiting, convulsions, LBP): as well as other

supportive measures:

If dicobalt edetate is available:

- Give 300 mg (20 mL) of 1.5% dicobalt edetate solution IV over 1 minute.
- Follow immediately with 50 mL Gluc 50%.

#### If dicobalt edetate is not available:

• Give 12.5 g sodium thiosulfate (50 mL of 25% or 25 mL of 50% solution) IV over 10 minutes.

# Severe poisoning (coma, fixed dilated pupils, cardiovascular collapse, respiratory failure, cyanosis):

If dicobalt edetate is available:

As well as other supportive measures:

- Give 300 mg (20 mL) of 1.5% dicobalt edetate solution IV over 1 minute.
- Follow immediately with 50 mL Gluc 50%.
- If there is only a partial response to dicobalt edetate 300 mg, or the patient relapses after recovery, give a further dose of dicobalt edetate 300 mg. If a second dose of dicobalt edetate is given there is ↑risk of cobalt toxicity but only if the diagnosis is not cyanide poisoning.

#### If dicobalt edetate is not available:

As well as other supportive measures:

- Give 300 mg (10 mL) of 3% sodium nitrite solution IV over 5-20 minutes.
- Follow with 12.5 g sodium thiosulfate (50 mL of 25% or 25 mL of 50% solution) IV over 10 minutes.
- A further dose of sodium thiosulfate 12.5 g IV over 10 minutes may then be given.
- A second dose of sodium nitrite should **not** be given because of the risk of excessive methaemoglobinaemia.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration.
- 3. Give by IV injection over 5-20 minutes monitoring the patient for adverse effects.
- 4. Give sodium thiosulfate as above.
- 5. The sodium nitrite dose should **not** be repeated.

# Sodium nitroprusside

#### 50-mg dry powder vials

- Sodium nitroprusside is a short-acting peripheral arteriolar and venous vasodilator that lowers peripheral resistance and *laterial* blood pressure.
- It is used in the management of hypertensive emergencies, for controlled hypotension in anaesthesia, and in acute or chronic heart failure.
- It is no longer marketed in the UK but is available from 'special-order' manufacturers or specialist importing companies.
- Treatment should be restricted to no more than 72 hours if possible to avoid toxicity.

#### **Pre-treatment checks**

- Do not use in compensatory hypertension such as arteriovenous bypass or coarctation of aorta.
- Use with caution, if at all, in patients with hepatic impairment, and in patients with low plasma cobalamin concentrations or Leber's optic atrophy.
- Caution in patients with impaired renal or pulmonary function and with particular caution in patients with impaired cerebrovascular circulation or ischaemic heart disease.

#### Biochemical and other tests

Blood pressure Bodyweight (in certain indications)

# Dose (no longer licensed in UK; doses specified are previously licensed doses)

**Hypertensive emergencies**: 0.5–1.5 microgram/kg/minute, increasing in steps of 500 nanograms/ kg/minute every 5 minutes to 0.5–8 microgram/kg/minute (use lower doses if the patient is already receiving other antihypertensives); stop if response is unsatisfactory with the maximum dose after 10 minutes. Treatment with an oral antihypertensive should be introduced as soon as possible.

Controlled hypotension in surgery: up to 1.5 micrograms/kg/minute.

**Cardiac failure**: 10–15 micrograms/minute, increasing by 10–15 micrograms/minute every 5–10 minutes as necessary; usual range 10–200 micrograms/minute (maximum 4 micrograms/kg/ minute), normally for a maximum of 3 days.

Calculation of infusion rate: NB: cardiac failure doses above are not given per kg bodyweight.

 $Infusion \ rate \ (mL/hour) = \frac{Bodyweight \ (kg) \times rate \ required \ (micrograms/kg/minute) \times 60}{Concentration \ of \ solution \ (micrograms/mL)}$ 

## Continuous intravenous infusion (large volume infusion)

#### Preparation and administration

The infusion and giving set must be protected from light. Any strong discoloration (bright orange, dark brown or blue) indicates serious degradation in the

presence of light and these solutions should be discarded.

- 1. Reconstitute each vial with 5 mL of the supplied solvent (use Gluc 5% if solvent is not supplied) and shake gently to dissolve to produce a solution containing 10 mg/mL.
- Withdraw 50 mg (5 mL) and add to 250, 500 or 1000 mL Gluc 5% infusion and mix well. The resulting solution will contain 200 micrograms/mL, 100 micrograms/mL or 50 micrograms/mL respectively.
- 3. The solution should be clear and may vary in colour from light brown, brownish-pink, light orange or straw. Inspect visually for particulate matter or discoloration prior to administration and discard if present. Any strong discoloration (bright orange, dark brown or blue) indicates serious degradation in the presence of light and these solutions should be discarded.
- 4. Wrap the prepared infusion immediately in foil (which may be provided) or other light-occlusive material, and do the same with the infusion set once attached.
- 5. Give by IV infusion via a volumetric infusion device at a rate appropriate for the indication. Continue to protect from light. Monitor the colour of the infusion periodically during administration and discard if discoloration has occurred.
- 6. Prepare a fresh infusion at least every 24 hours if required.
- 7. Treatment should not be stopped abruptly; taper off over 30 minutes to avoid rebound effects.

#### Continuous intravenous infusion via a syringe pump

#### Preparation and administration

The infusion and giving set must be protected from light. Any strong discoloration (bright orange, dark brown or blue) indicates serious degradation in the presence of light and these solutions should be discarded.

- 1. Reconstitute each vial with 5 mL supplied solvent (use Gluc 5% if solvent is not supplied) and shake gently to dissolve to produce a solution containing 10 mg/mL.
- 2. Withdraw 50 mg (5 mL) and make up to 50 mL in a syringe pump with Gluc 5%.
- 3. Mix well to give a solution containing 1 mg/mL.
- 4. The solution should be clear and may vary in colour from light brown, brownish-pink, light orange or straw. Inspect visually for particulate matter or discoloration prior to administration and discard if present. Any strong discoloration (bright orange, dark brown or blue) indicates serious degradation in the presence of light and these solutions should be discarded.
- 5. Wrap the prepared syringe immediately in foil (which may be provided) or other light-occlusive material, and do the same with the infusion set once attached.
- Give by IV infusion at a rate appropriate for the indication. Continue to protect from light. Monitor the colour of the infusion periodically during administration and discard if discoloration has occurred.
- 7. Prepare a fresh syringe at least every 24 hours if required.
- 8. Treatment should not be stopped abruptly; taper off over 30 minutes to avoid rebound effects.

# Sodium stibogluconate

#### 100 mg/mL solution in 100-mL vials

- · Sodium stibogluconate is a pentavalent antimony compound.
- It is used as first-line treatment for all forms of leishmaniasis except Leishmania aethiopica infections.
- Doses are expressed as pentavalent antimony: Sodium stibogluconate injection contains pentavalent antimony 100 mg/mL.

#### **Pre-treatment checks**

- · Do not give if a serious reaction was experienced to the previous dose.
- Caution in patients with cardiovascular disease, a history of ventricular arrhythmias or other risk factors that predispose towards QT prolongation.
- · Caution in existing infections, e.g. pneumonia should be actively treated concomitantly.

#### Biochemical and other tests

ECG (if unavailable the risks and benefits of therapy will need to be assessed) LFTs

Renal function: not to be given in moderate to severe renal impairment. Unfortunately the degree of renal impairment at which the drug should not be given (or should be given at a reduced dose) is poorly defined and no precise data is available based on creatinine clearance.

#### Dose

**Visceral leishmaniasis:** 20 mg (0.2 mL)/kg up to a maximum of 850 mg (8.5 mL) by IM or IV injection daily for a minimum period of 20 days. Patients should be examined for evidence of relapse after 2 and 6 months and in Africa again after 12 months.

Expert advice should be sought for dosing information in other forms of leishmaniasis as treatment regimens vary by species and geographical source of infection.

Dose in renal impairment: avoid in 'significant' renal impairment.

## Intramuscular injection (preferred route)

#### Preparation and administration

- Withdraw the required dose into a syringe immediately before administration through a filter of 5 microns or less (if the volume exceeds 10 mL the dose should be split between two sites<sup>1</sup>).
- 2. Remove the filter and give by deep IM injection into the buttock or thigh. Rotate injection sites for subsequent injections.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose into a syringe immediately before administration through a filter of 5 microns or less.
- 2. Remove the filter and replace with a fine needle, which may help to avoid thrombophlebitis.
- 3. Give by slow IV injection over at least 5 minutes.

# Sodium thiosulfate (sodium thiosulphate, disodium thiosulfate)

#### $2.5\,g/10\,mL$ (25%) or $5\,g/10\,mL$ (50%) solution in ampoules

- Sodium thiosulfate is used in the treatment of cyanide poisoning. It acts as a sulfur-donating substrate for the enzyme rhodanese, which catalyses the conversion of cyanide to relatively non-toxic thiocyanate, and thus accelerates the detoxification of cyanide.
- It may be effective alone in less severe cases of cyanide poisoning, but it may be used with dicobalt
  edetate or sodium nitrite in more severe poisoning (see below).

#### **Pre-treatment checks**

• It is important to be aware whether any cyanide antidote therapy has been given in the prehospital setting as repeat doses of some antidotes can cause serious side-effects.

#### 770 | Sodium thiosulfate

## Doses of cyanide poisoning antidotes (see relevant entries)<sup>1</sup>

It is essential to consult a poisons information service, e.g. Toxbase at www.toxbase.org (password or registration required) for full details of the management of cyanide toxicity.

#### Mild poisoning (nausea, dizziness, drowsiness, hyperventilation, anxiety):

- Observe.
- Give 12.5 g sodium thiosulfate (50 mL of 25% or 25 mL of 50% solution) IV over 10 minutes.

# **Moderate poisoning (reduced conscious level, vomiting, convulsions**, **JBP):** as well as other supportive measures:

If dicobalt edetate is available:

- Give 300 mg (20 mL) of 1.5% dicobalt edetate solution IV over 1 minute.
- · Follow immediately with 50 mL Gluc 50%.

#### If dicobalt edetate is not available:

• Give 12.5 g sodium thiosulfate (50 mL of 25% or 25 mL of 50% solution) IV over 10 minutes.

# Severe poisoning (coma, fixed dilated pupils, cardiovascular collapse, respiratory failure, cyanosis):

*If dicobalt edetate is available:* 

As well as other supportive measures:

- Give 300 mg (20 mL) of 1.5% dicobalt edetate solution IV over 1 minute.
- · Follow immediately with 50 mL Gluc 50%.
- If there is only a partial response to dicobalt edetate 300 mg, or the patient relapses after recovery, give a further dose of dicobalt edetate 300 mg. If a second dose of dicobalt edetate is given, there is *risk* of cobalt toxicity but only if the diagnosis is not cyanide poisoning.

#### If dicobalt edetate is not available:

As well as other supportive measures:

- Give 300 mg (10 mL) of 3% sodium nitrite solution IV over 5-20 minutes.
- Follow with 12.5 g sodium thiosulfate (50 mL of 25% or 25 mL of 50% solution) IV over 10 minutes.
- A further dose of sodium thiosulfate 12.5 g IV over 10 minutes may then be given.
- A second dose of sodium nitrite should **not** be given because of the risk of excessive methaemoglobinaemia.

#### Intravenous injection

#### Preparation and administration

- 1. Give sodium nitrite first if appropriate (see above).
- 2. Withdraw the required dose.
- 3. Give by IV injection over about 10 minutes.

# Sodium valproate (valproate sodium)

#### 100 mg/mL solution in 3-mL and 10-mL ampoules (Episenta) 400-mg dry powder vials with 4 mL WFI (Epilim)

- Sodium valproate is an antiepileptic drug.
- It is used to treat all forms of epilepsy as monotherapy or as an adjunct to other antiepileptic agents.
- It is usually used parenterally in patients normally maintained on sodium valproate when the oral route is temporarily unavailable.

#### 772 | Sodium valproate

#### Pre-treatment checks

- Do not give if there is active liver disease or family history of severe hepatic dysfunction, and in acute porphyria.
- Caution in SLE.
- Use extreme caution in pregnancy (may cause congenital malformations).

Biochemical and other tests (not all are necessary in an emergency situation)

| FBC - ensure there is no excess potential for | Pregnancy test – where appropriate    |
|-----------------------------------------------|---------------------------------------|
| bleeding                                      | Renal function: U, Cr, CrCl (or eGFR) |
| LFTs                                          |                                       |

#### Dose

For existing epilepsy patients switched from oral maintenance to parenteral dosing:

· No adjustment of dose or frequency is necessary.

**Patients previously established on oral therapy:** doses are given by IV injection or infusion at the same dose and frequency as previous oral therapy.

**Initiation of treatment in patients temporarily unable to tolerate oral therapy:** 400–800 mg (up to 10 mg/kg) by slow IV injection, followed by intermittent IV infusion. Increase dose gradually up to a maximum of 2.5 g daily.

Dosage in hepatic impairment: avoid if possible.

#### Intermittent intravenous infusion

#### Preparation and administration

- If used, reconstitute dry powder vials with 3.8 mL WFI (provided) to give a solution containing 100 mg/mL (if the full 4 mL of diluent is used then the resultant solution contains 95 mg/mL).
- 2. Add the required dose to at least 50 mL of compatible infusion fluid (usually 100 mL NaCl 0.9%).
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV infusion over 60 minutes via volumetric infusion device at a maximum rate of 20 mg/ minute.

#### Intravenous injection

#### Preparation and administration

- If used, reconstitute dry powder vials with 3.8 mL WFI (provided) to give a solution containing 100 mg/mL (if the full 4 mL of diluent is used then the resultant solution contains 95 mg/mL).
- 2. Withdraw the required dose. It may be further diluted with NaCl 0.9% or Gluc 5% to facilitate slow administration.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over 3-5 minutes.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

## **Bibliography**

SPC Epilim intravenous (accessed 2 February 2010). SPC Episenta solution for injection (sodium valproate) (accessed 2 February 2010).

# Starch, etherified

#### See products listed in Table S3 below (other products may be available)

- Etherified starch preparations are plasma volume expanders. Most 6% solutions produce an expansion in plasma volume slightly in excess of the volume infused; the 10% solutions and HyperHAES produce an expansion of plasma volume of about 1.5 times the infused volume.
- Duration of effect is dependent on the molecular weight of the starch used; products containing higher-molecular-weight starches are generally retained in the plasma for longer.
- The etherified starches are used in the initial short-term management of hypovolaemic shock caused by conditions such as burns, septicaemia, haemorrhage, acute trauma or surgery. They are not a substitute for whole blood or plasma and have no oxygen-carrying capacity; blood products should be given as soon as available if appropriate.

#### **Pre-treatment checks**

- Do not give to patients likely to develop circulatory overload, e.g. congestive cardiac failure, renal failure and pulmonary oedema, patients with intracranial bleeds or those undergoing dialysis.
- Caution if at risk of liver disease and bleeding disorders.
- · Dehydration should be corrected prior to or during treatment.
- In metabolic alkalosis and clinical situations where alkalisation should be avoided, saline-based solutions should be preferred over those containing alkalising agents.

#### Biochemical tests (not all are necessary in an emergency situation)

Electrolytes: Na FBC Renal function: U, Cr, CrCl (or eGFR)

#### Dose

**Hypovolaemic shock by IV infusion:** the volume given and rate of infusion will depend on the condition of the patient. Prolonged infusion should be avoided where possible because of the risk of depletion of plasma proteins, electrolytes and coagulation factors.

- · Hetastarch 6%: 500-1000 mL, usual daily maximum 1500 mL.
- Pentastarch 6%: up to 2500 mL daily.
- Pentastarch 10%: up to 1500 mL daily; maximum suggested rate 20 mL/kg/hour.
- Tetrastarch 6%: up to 50 mL/kg daily.
- · Tetrastarch 10%: up to 30 mL/kg daily.

**Hypovolaemic shock by rapid IV infusion (HyperHAES):** 4 mL/kg (or 250 mL for a 60–70 kg patient) as a single dose over 2–5 minutes. Repeated infusions are not recommended. Follow immediately by the administration of appropriate isotonic replacement fluids, dosed according to the needs of the patient.

## Intravenous infusion (not HyperHAES)

#### Preparation and administration

- The infusion is pre-prepared for use. It should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 2. Give by IV infusion at the required rate. Some manufacturers recommend that owing to the risk of anaphylaxis, the first 10–20 mL should be given slowly and the patient observed closely.
- 3. Discard any unused portion. Do not reconnect partially used infusion containers.

## Intravenous infusion (HyperHAES only)

#### Preparation and administration

Administration via a central line is preferable but a peripheral line may be used.

- The infusion is pre-prepared for use. It should be clear to slightly opalescent, colourless to slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 2. Give the required dose by rapid IV infusion over 2–5 minutes; pressure may be applied to the container to hasten administration.
- 3. Discard any unused portion. Do not reconnect partially used infusion containers.
- 4. Follow immediately by the administration of appropriate isotonic replacement fluids.

# **Streptokinase**

## 250 000-unit dry powder vials; 750 000-unit dry powder vials; 1.5 million-unit dry powder vials

- Streptokinase is a plasminogen activator derived from beta-haemolytic streptococci. It has thrombolytic activity.
- It is licensed for the dissolution of clots in MI, acute massive PE, peripheral arterial thromboembolism, and central retinal venous or arterial thrombosis.
- It may also be used to clear cannulas and shunts, and may be given intrapleurally as adjunct in empyema (all unlicensed).

## **Pre-treatment checks**

Streptokinase is contraindicated in the following:

- Existing or recent internal haemorrhages, all forms of ↓blood coagulability, in particular spontaneous fibrinolysis and extensive clotting disorders.
- Recent cerebrovascular insults, intracranial or intraspinal surgery, recent head trauma.
- · Intracranial neoplasm, known neoplasm with risk of haemorrhage.
- · Arteriovenous malformation or aneurysm.
- · Acute pancreatitis, severe liver or kidney damage.
- Uncontrollable 
   †BP with systolic values >200 mmHg and/or diastolic values >100 mmHg or
   hypertensive retinal changes grades III/IV.
- Recent implantation of vessel prosthesis.
- Simultaneous treatment with oral anticoagulants (INR > 1.3).
- Endocarditis or pericarditis.
- Known haemorrhagic diathesis.
- Recent major operations (6th to 10th postoperative day, depending on the severity of surgical intervention), invasive operations, e.g. recent organ biopsy, long-term (traumatic) closed-chest cardiac massage.
- Caution: repeat dosing may not be effective >4 days after initial exposure, with ↑risk of hypersensitivity reactions after this time owing to the formation of anti-streptokinase antibodies. Use of an alternative non-antigenic thrombolytic is recommended for repeat thrombolysis after this time.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Blood pressure                        | Thrombin time (TT), activated partial thrombo-  |
|---------------------------------------|-------------------------------------------------|
| LFTs                                  | plastin time (APTT), haematocrit and platelet   |
| Renal function: U, Cr, CrCl (or eGFR) | count (before commencing thrombolytic therapy). |

## Dose

Streptokinase is antigenic and allergic reactions are common. Consider prophylactic administration of parenteral corticosteroid when used systemically.

**Myocardial infarction (initiated within 12 hours of symptom onset):** 1.5 million units by IV infusion over 60 minutes.

**DVT, PE, acute arterial thromboembolism, central retinal venous/arterial thrombosis:** 250 000 units by IV infusion over 30 minutes, followed by a maintenance dose 100 000 units/hour by IV infusion for 12–72 hours according to condition and response (12 hours is usually adequate for retinal thrombus). This may be followed with heparin by IV infusion, oral anticoagulants or platelet deaggregants as appropriate.

For other regimens, see product literature.

Cannula occlusion (unlicensed): 250 000 units (see below for method).

NB: Urokinase is licensed for this indication (see the Urokinase monograph).

**Clearance of thoracic empyema and pleural effusion (unlicensed):** 250 000 units intrapleurally as a single dose or once or twice daily for 3–5 days.<sup>1</sup>

## Intravenous infusion

#### Preparation and administration

- 1. Check that you have selected the correct strength of vial.
- Reconstitute the vial with 5 mL NaCl 0.9%, directing the solvent against the sides of the vial rather than directly into the drug powder to minimise frothing.
- 3. Roll and tilt the vial gently to dissolve the powder. Do not shake (to avoid foam formation).
- The solution produced contains: 300 000 units/mL (1.5 million-unit vial) 150 000 units/mL (750 000-unit vial) 50 000 units/mL (250 000-unit vial).
- 5. Withdraw the required dose and add to a suitable volume of NaCl 0.9% (usually 100 mL) or make up to a suitable volume in a syringe pump. Mix well.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV infusion via a volumetric infusion device or syringe pump at a rate appropriate to the indication. Do not use a drop-counting infusion device because streptokinase affects drop size.

### Clearance of occluded intravenous cannulas (unlicensed)

#### Preparation and administration

- 1. Add 2 mL NaCl 0.9% to a 250 000-unit vial, directing the solvent against the sides of the vial rather than directly into the drug powder to minimise frothing.
- 2. Roll and tilt the vial gently to dissolve the powder. Do not shake (to avoid foam formation).
- 3. Infuse the 2mL dose over 25–35 minutes directly into the cannula, clamp for 2 hours, then aspirate and flush with NaCl 0.9%.

## Intrapleural administration (unlicensed)

#### Preparation and administration

- 1. Add 5 mL NaCl 0.9% to a 250 000-unit vial, directing the solvent against the sides of the vial rather than directly into the drug powder to minimise frothing.
- 2. Roll and tilt the vial gently to dissolve the powder. Do not shake (to avoid foam formation).
- 3. Withdraw 250 000 units and make up to 50 mL with NaCl 0.9% in a 50-mL syringe.
- 4. Introduce into the intrapleural space via an intercostal tube.
- 5. Clamp and release after 2-4 hours.
- 6. The patient should be given a streptokinase exposure card.

# **Streptomycin**

#### 1-g dry powder vials

- · Streptomycin sulfate is an aminoglycoside antibacterial.
- It may be used with other antimycobacterials in the initial phase of treatment of tuberculosis.
- It may also be effective in the treatment of plague, tularaemia and, with a tetracycline, in brucellosis.
- Doses are expressed in terms of the base: Streptomycin  $1 g \equiv 1.25 g$  streptomycin sulfate.

## **Pre-treatment checks**

- Do not give in myasthenia gravis.
- Ensure good hydration status (dehydration ↑risk of toxicity).

#### Biochemical and other tests

| Baseline  | check    | of | auditory | (audiogram) | and | Electrolytes: serum K, Ca, Mg         |
|-----------|----------|----|----------|-------------|-----|---------------------------------------|
| vestibula | r functi | on |          |             |     | FBC                                   |
| Bodyweig  | ght      |    |          |             |     | Renal function: U, Cr, CrCl (or eGFR) |

In the USA, Romberg testing of neurological function is also recommended.<sup>1</sup>

## Dose

**Tuberculosis (>50 kg and <40 years):** 15 mg/kg daily by IM injection (maximum of 1 g daily). **Tuberculosis (<50 kg or >40 years):** 10 mg/kg daily by IM injection (maximum 750 mg daily). **Other infections**: seek specialist advice.

Dose in renal impairment: adjusted according to creatinine clearance:<sup>2</sup>

- CrCl >20–50 mL/minute: give every 24–72 hours; dose according to levels.
- CrCl 10-20 mL/minute: give every 24-72 hours; dose according to levels.
- CrCl <10 mL/minute: give every 72–96 hours; dose according to levels.

## Intramuscular injection

See Special handling below.

Preparation and administration

1. Determine the required dose then reconstitute each vial with WFI to produce a suitable concentration of streptomycin, i.e.:

| Volume of WFI<br>added                          | 4.2 mL    | 3.2 mL    | 1.8 mL    |
|-------------------------------------------------|-----------|-----------|-----------|
| Approximate<br>concentration of<br>streptomycin | 200 mg/mL | 250 mg/mL | 400 mg/mL |

- 2. Withdraw the required dose.
- 3. Give by deep IM injection into a large muscle mass, preferably the upper outer quadrant of the buttock or the mid-lateral thigh (in children use mid-lateral thigh). Do not inject into the lower or mid-third of the upper arm. Rotate injection sites for subsequent injections.

| Technical information |                                         |  |  |
|-----------------------|-----------------------------------------|--|--|
| Incompatible with     | Not relevant                            |  |  |
| Compatible with       | Solutions: WFI                          |  |  |
| рН                    | 4.5-7                                   |  |  |
| Sodium content        | Nil                                     |  |  |
| Storage               | Store below 30°C in original packaging. |  |  |

(continued)

## 784 | Streptomycin

| Technical information (continued) |                                                                                                                                             |  |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|--|
| Displacement value                | Approximately 0.8 mL/1 g                                                                                                                    |  |
| Special handling                  | May cause severe dermatitis in sensitised persons. Anyone who handles streptomycin frequently should wear masks and rubber gloves.          |  |
| Stability after preparation       | From a microbiological point of view, should be used immediately; however, reconstituted vials are stable at room temperature for 24 hours. |  |

## Monitoring

| Measure                              | Frequency                                                                                   | Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

# **Sumatriptan**

## 12 mg/mL solution in 0.5-mL prefilled syringe and auto-injector; 12 mg/mL solution in 0.5-mL cartridges

- Sumatriptan succinate is a 5HT<sub>1</sub> agonist that causes vasoconstriction of cranial arteries.
- It is used as monotherapy for acute migraine, with or without aura, and for cluster headaches.
- Overusage of sumatriptan can lead to an exacerbation of symptoms.

## **Pre-treatment checks**

- Do not give if previous CVA or TIA; peripheral vascular disease; moderate and severe *†BP*, in ischaemic heart disease, previous myocardial infarction, coronary vasospasm (including Prinzmetal's angina).
- If cardiovascular disease is present, consider giving the first dose under medical supervision (possibly with ECG monitoring after administration as asymptomatic cardiac ischaemia can occur).
- · Caution if there is a history of seizures or sensitivity to sulfonamides.
- Not recommended in elderly patients (>65).

#### Biochemical tests

LFTs – avoid in severe impairment Renal function–use with caution (renally excreted)

### Dose

**Migraine and cluster headache:** 6 mg by SC injection as soon as possible after onset of headache symptoms; if symptoms recur, the dose may be repeated after at least 1 hour (maximum 12 mg in 24 hours). If no response is seen to the initial dose, a second dose should not be used for the same attack.

## **Subcutaneous injection**

#### Preparation

- 1. Open the case; break the red seal over one of the cartridges and open lid.
- Remove the auto-injector pen if the white rod is sticking out from the end of the pen, replace the pen and push firmly then remove the pen from the case.
- 3. Push the pen into the cartridge pack and turn clockwise as far as it will turn (approximately half a turn).
- 4. Pull the pen with the cartridge attached from the case it may be necessary to pull quite hard.
- 5. Do not return the pen to the case until the dose has been administered, to avoid needle damage.

#### Administration

- 1. Place the blue end of the pen over a clean area of skin that has sufficient SC tissue to accommodate the needle, i.e. 5–6 mm (usually the outer thigh). Avoid inadvertent IV administration (can cause vasospasm resulting in arrhythmias, ECG changes or MI).
- Press the pen firmly so that the grey part of the pen moves over the blue part to cover it the safety catch has now been released.
- 3. Press the blue button on top of the pen to release the drug count to 10 (slowly) holding the pen very still and secure. Removing the pen too soon will result in the dose being wasted.
- 4. Remove the pen, avoiding touching the needle.
- 5. Push the pen back into the cartridge slot and unscrew the pen by turning it anticlockwise and remove the pen.
- 6. Close the blue lid over the used cartridge and return the pen to the carry-case slot.

## Bibliography

SPC Imigran injection, Subject, GlaxoSmithKline UK (accessed 21 April 2008).

## **Tacrolimus**

#### 5 mg/mL solution in ampoules

- Tacrolimus is a potent macrolide immunosuppressant derived from *Streptomyces tsukubaensis* with actions similar to ciclosporin.
- It is used to prevent or manage organ rejection in transplant patients, but it is also licensed in some countries for use in treatment resistant myasthenia gravis, rheumatoid arthritis and Crohn disease.

#### **Pre-treatment checks**

Do not give if there is hypersensitivity to tacrolimus, macrolides or polyethoxylated castor oils, and in pregnancy and breast feeding.

#### Biochemical and other tests

Blood glucose ECG Electrolytes: serum K, Na, Mg, Ca, PO<sub>4</sub> FBC LFTs (in severe hepatic impairment (Child–Pugh score of 10 or higher) lower doses may be required) Neurological and visual status Renal function: U, Cr

#### Dose

IV administration carries a risk of anaphylaxis and should be reserved for patients who cannot tolerate the oral route. Tacrolimus should be given IV for no more than 7 days. In transplant patients it is crucial to seek specialist advice on any route or dose adjustments.

**Prophylaxis of liver transplant rejection starting 12 hours after transplantation:** initially 10–50 micrograms/kg daily by continuous IV infusion over 24 hours for a maximum of 7 days. Adjust dose according to response and blood level monitoring. Change to oral therapy (via NG tube if necessary) as soon as the enteral route becomes available.

**Prophylaxis of kidney transplant rejection starting within 24 hours of transplantation:** initially 50–100 micrograms/kg daily by continuous IV infusion over 24 hours for a maximum of 7 days. Adjust dose according to response and blood level monitoring. Change to oral therapy (via NG tube if necessary) as soon as the enteral route becomes available.

**Prophylaxis of heart transplant rejection (with or without antibody induction) starting within 5 days of transplantation:** 10–20 micrograms/kg daily by continuous IV infusion over 24 hours for a maximum of 7 days. Adjust dose according to response and blood level monitoring. Change to oral therapy (via NG tube if necessary) as soon as the enteral route becomes available. **Rejection therapy:** seek specialist advice.

**Dose in renal impairment:** no adjustment is required for patients with impaired renal function; however, tacrolimus is nephrotoxic so monitoring of renal function is required.

**Dose in hepatic impairment:** in severe liver impairment keep blood trough levels within the recommended range.

## **Continuous intravenous infusion**

### Preparation and administration

Tacrolimus must never be given undiluted and must always be given by continuous infusion. PVC containers and giving sets should not be used.

- Withdraw the required dose and add to a suitable volume of NaCl 0.9% or Gluc 5% to give a solution containing 4–100 micrograms/mL (the total volume of infusion over a 24-hour period should be in the range 20–500 mL). Mix well.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 24 hours. Observe continuously for at least the first 30 minutes following initiation of the infusion and at frequent intervals for possible allergic reactions.

### **Technical information** PVC containers and giving sets should not be used. Incompatible with Aciclovir, ganciclovir. Compatible with Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5% Y-site: No information but likely to be unstable pН 6.33 when diluted to 10 micrograms/mL in NaCl 0.9%<sup>1</sup> Sodium content Nil Excipients Contains ethanol (may interact with metronidazole, possible religious objections). Contains polyoxyl castor oils (have been associated with severe anaphylactic reactions). Store below 25°C in original packaging. Storage Stability after Use prepared infusions immediately. preparation

#### Monitoring

## Talc, sterile

#### 4-g and 5-g powder (other sizes may be available); 4-g Steritalc PF Puffer

- · Sterile talc is an unlicensed product.
- It may be used as a sclerosant for pleurodesis in the management of malignant pleural effusions.<sup>1</sup>

#### **Pre-treatment checks**

- · An intercostal tube is inserted and the pleural effusion is drained.
- · Administration of an anxiolytic should be considered prior to commencing pleurodesis.
- Lidocaine (3 mg/kg up to a maximum of 250 mg) has been given intrapleurally just prior to sclerosant administration.<sup>1</sup>

#### Biochemical and other tests

Chest X-ray: to ensure complete lung expansion and to confirm the position of the tube.

#### Dose

**Standard dose:** 2–5 g of sterile talc is made into slurry and administered into the pleural space (doses used have ranged from 1 to 10 g).

If using the Steritalc puffer, a dose of 4 g can be administered directly into the pleural cavity.

### Intrapleural -- slurry

#### Preparation and administration

- 1. Mix the required dose of sterile talc with 30 mL WFI using a bladder syringe.
- 2. Instil via the intercostal tube.
- 3. Clamp the tube for 1 hour and consider patient rotation to allow dispersion of the talc.
- 4. Release the clamp and drain the fluid off.

## Intrapleural -- insufflation (Steritalc PF Puffer)

#### Preparation and administration<sup>2</sup>

- 1. Fix the silicone connector (included) onto the internal nozzle of the puffer.
- 2. Screw the male Luer-Lok connector to its maximum on the cannula while firmly holding it.
- Hold the cannula and the puffer together and press smoothly several times on the puffer to spray Steritalc homogeneously into the pleural space.

### 794 | Talc, sterile

## Teicoplanin

#### 200-mg and 400-mg dry powder vials with solvent (WFI)

- · Teicoplanin is a glycopeptide antibiotic (it is a mixture of several components).
- It may be used as an alternative to vancomycin where other drugs cannot be used in the treatment
  of serious Gram-positive infections. These include the treatment and prophylaxis of infective
  endocarditis; peritonitis associated with continuous ambulatory peritoneal dialysis and suspected
  infection in neutropenic or otherwise immunocompromised patients.

#### **Pre-treatment checks**

Caution in hypersensitivity to vancomycin.

#### Biochemical and other tests

FBC LFTs Renal function: U, Cr, CrCl (or eGFR)

#### Dose

**Severe infections (joint and bone infection, septicaemia, endocarditis):** 400 mg by IV injection or infusion every 12 hours for three doses followed by 400 mg daily either by IM or IV injection or IV infusion (for patients >85 kg dose at 6 mg/kg). In some situations (e.g. severe burns, endocarditis) doses up to 12 mg/kg by IV injection or infusion have been given.

**Moderate infections (skin and soft-tissue infection, urinary tract infection, lower respiratory tract infection):** 400 mg by IM or IV injection or IV infusion on the first day followed by 200 mg daily thereafter (for patients >85 kg, dose at 3 mg/kg).

**Surgical prophylaxis:** 400 mg by IV injection as a single dose at induction of anaesthesia. Check local policies.

**Dose in renal impairment:** dose according to indication up to the fourth day of treatment then reduce the dose according to creatinine clearance:<sup>1</sup>

- CrCl >20-50 mL/minute: dose as in normal renal function.
- CrCl 10-20 mL/minute: give the normal loading dose then 200-400 mg every 24-48 hours.
- CrCl <10 mL/minute: give the normal loading dose then 200–400 mg every 48–72 hours.

**Peritonitis in continuous ambulatory peritoneal dialysis:** if the patient is febrile, give a 400-mg loading dose by IV injection or infusion, then 20 mg/L per bag for the first week, 20 mg/L in alternate bags for the second week and 20 mg/L in the overnight dwell bag only for a third week.

## Intravenous injection

#### Preparation and administration

- 1. Slowly add the entire contents of the solvent provided to the vial of teicoplanin.
- Roll gently until the powder is completely dissolved (if the solution becomes foamy, leave it to stand for 15 minutes to settle). After reconstitution a 200-mg vial contains 200 mg/3 mL and a 400-mg vial contains 400 mg/3 mL.
- 3. Withdraw the required dose.
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by IV injection over 3-5 minutes.

## Intermittent intravenous infusion

#### Preparation and administration

- 1. Slowly add the entire contents of the solvent provided to the vial of teicoplanin.
- Roll gently until the powder is completely dissolved (if the solution becomes foamy, leave it to stand for 15 minutes to settle). After reconstitution a 200-mg vial contains 200 mg/3 mL and a 400-mg vial contains 400 mg/3 mL.
- Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually 100 mL NaCl 0.9% or Gluc 5%).
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by IV infusion over 30 minutes.

## Intramuscular injection

#### Preparation and administration

- 1. Slowly add the entire contents of the solvent provided to the vial of teicoplanin.
- Roll gently until the powder is completely dissolved (if the solution becomes foamy, leave it to stand for 15 minutes to settle). After reconstitution a 200-mg vial contains 200 mg/3 mL and a 400-mg vial contains 400 mg/3 mL.
- 3. Withdraw the required dose.
- 4. Give by deep IM injection into a large muscle.

## **Continuous ambulatory peritoneal dialysis**

#### Preparation and administration

As for IM injection and add the required dose to dialysis solution.

## **Bibliography**

SPC Targocid 200 mg and 400 mg (accessed 3 April 2009).

## Temocillin

#### 1-g dry powder vials

- Temocillin sodium is a semisynthetic penicillin, and is resistant to a wide range of beta-lactamases.
- It is used to treat infections caused by beta-lactamase-producing strains of Gram-negative aerobic bacteria (including those resistant to third-generation cephalosporins).
- In mixed infections where Gram-positive or anaerobic bacteria are also likely it may be given with
  other appropriate antibacterial agents.
- Doses are expressed in terms of the base: Temocillin  $1 g \cong 1.11 g$  temocillin sodium.

### **Pre-treatment checks**

Check for history of allergy/hypersensitivity to penicillins and use with caution if the patient is sensitive to other beta-lactam antibiotics.

#### Biochemical and other tests

Renal function: U, Cr, CrCl (or eGFR)

## Dose

**Standard dose:** 1–2 g by IM or IV injection or IV infusion every 12 hours.

**Uncomplicated urinary tract infections:** 1 g by IM or IV injection or IV infusion every 24 hours. **Dose in renal impairment:** 

- CrCl >30-50 mL/minute: dose as in normal renal function.
- CrCl 10-30 mL/minute: 1-2 g every 24 hours.
- CrCl <10 mL/minute: 1-2 g every 48 hours.

## Intravenous injection

#### Preparation and administration

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Add 20 mL WFI to vial and shake vigorously.
- 2. Withdraw the required dose.
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over 3-4 minutes.

## Intermittent intravenous infusion

Preparation and administration

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Add 20 mL WFI to vial and shake vigorously.
- Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually 100 mL NaCl 0.9%).
- 3. The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 30-40 minutes.

## Intramuscular injection (maximum dose 1 g)

#### Preparation and administration

- 1. Add 2 mL WFI to vial and shake vigorously.
- 2. Withdraw the required dose.
- 3. Give by IM injection. If pain occurs, 0.5–1% lidocaine may be used for reconstitution (see the Lidocaine monograph for cautions and monitoring).

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

## **Bibliography**

SPC Negaban 1 g, powder for solution for injection/infusion, published 1 September 2003.

# **Tenecteplase**

### 8000 units (40 mg) dry powder vial with 8 mL WFI in pre-filled syringe 10 000 units (50 mg) dry powder vial with 10 mL WFI in pre-filled syringe

- · Tenecteplase is a fibrin-specific plasminogen activator. It has thrombolytic activity.
- · It is licensed for the dissolution of clots in STEMI.
- Tenecteplase doses are expressed in units specific to tenecteplase, which are not directly comparable with units of other thrombolytic agents.

### **Pre-treatment checks**

- Contraindicated in recent haemorrhage, trauma, or surgery (including dental extraction), coagulation defects, bleeding diatheses, aortic dissection, aneurysm, coma, history of cerebrovascular disease especially recent events or with any residual disability, recent symptoms of possible peptic ulceration, heavy vaginal bleeding, severe *†*BP, active pulmonary disease with cavitation, acute pancreatitis, pericarditis, bacterial endocarditis, severe liver disease, and oesophageal varices.
- Use with caution if there is a risk of bleeding including that from venepuncture or invasive procedures.
- Caution in external chest compression, pregnancy, elderly patients, <sup>†</sup>BP, conditions in which thrombolysis might give rise to embolic complications such as enlarged left atrium with atrial fibrillation (risk of dissolution of clot and subsequent embolisation), and recent or concurrent use of drugs that <sup>†</sup>risk of bleeding.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure and pulse – do not give if systolic BP >160. Bodyweight LFTs

#### Dose

**Acute myocardial infarction:** a single weight-based dose (Table T1) given by IV injection as soon as possible (within 6 hours) after the onset of symptoms.

| Bodyweight (kg) | Tenecteplase<br>(units) | Tenecteplase<br>(mg) | Volume of reconstituted solution (mL) |
|-----------------|-------------------------|----------------------|---------------------------------------|
| <60             | 6 000                   | 30                   | 6                                     |
| 60 to 69        | 7 000                   | 35                   | 7                                     |
| 70 to 79        | 8 000                   | 40                   | 8                                     |
| 80 to 89        | 9 000                   | 45                   | 9                                     |
| ≥90             | 10 000                  | 50                   | 10                                    |

 Table T1
 Weight-based dosing of tenecteplase

Dose in hepatic impairment: do not give in severe disease.

## Intravenous injection

#### Preparation and administration

Tenecteplase is incompatible with Gluc solutions.

- 1. Select the correct vial size according to bodyweight: 8000 units for <80 kg, 10 000 units for 80 kg and over.
- 2. Screw the pre-filled syringe onto the vial adapter and penetrate the vial stopper in the middle with the spike of the vial adapter.
- 3. Add the WFI into the vial by pushing the syringe plunger down slowly to avoid foaming.
- 4. Reconstitute by swirling gently to give a solution containing 1000 units/mL.
- Immediately prior to use invert the vial with the syringe still attached, so that the syringe is below the vial.
- 6. Transfer the appropriate volume of reconstituted solution into the syringe, based on the patient's weight (see Table T1).
- 7. Disconnect the syringe from the vial adapter.
- 8. The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 9. Give by IV injection over 10 seconds.

SPC Metalyse (accessed 31 March 2010).

## **Terbutaline sulfate**

#### 500 micrograms/mL solution in 1-mL ampoules

- Terbutaline sulfate is a direct-acting sympathomimetic with mainly beta-adrenergic activity and a selective action on beta<sub>2</sub>-receptors.
- It can be given by various parenteral routes in the management of severe bronchospasm and by IV
  infusion to delay uncomplicated premature labour.

#### **Pre-treatment checks**

- Avoid use in patients with underlying severe heart disease, e.g. ischaemic heart disease, arrhythmia
  or severe heart failure.
- · Use with caution in thyrotoxicosis.
- In asthma, use should be combined with oxygen and corticosteroid therapy.
- · Hypoglycaemic therapy in patients with diabetes may require review.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Blood glucose            | Electrolytes: serum K                      |
|--------------------------|--------------------------------------------|
| Blood pressure and pulse | Respiratory function: ABGs, pulse oximetry |

#### Dose

**Severe bronchospasm:** 250–500 micrograms by SC or slow IV injection up to 4 times daily. Alternatively, 90–300 micrograms/hour by IV infusion for 8–10 hours adjusted according to clinical response and heart rate.

**Premature labour:** Gluc 5% should be used to prepare the infusion to *\*risk of maternal pulmonary oedema.

Initially 5 micrograms/minute (300 micrograms/hour) by IV infusion increasing in steps of 2.5 micrograms/minute at 20-minute intervals until contractions have ceased.

More than 10 micrograms/minute is rarely required; 20 micrograms/minute should not be exceeded. Continue for 1 hour then gradually decrease every 20 minutes in steps of 2.5 micrograms/minute to the lowest dose that maintains suppression and continue at this dose for 12 hours. Continue with oral therapy or SC injections if required, bearing in mind  $\uparrow$ risk to the mother after 48 hours of treatment. **Dose in renal impairment:** adjusted according to creatinine clearance:<sup>1</sup>

- CrCl >20–50 mL/minute: reduce the parenteral dose by 50%.
- CrCl 10-20 mL/minute: reduce the parenteral dose by 50%.
- CrCl <10 mL/minute: avoid the parenteral route.

## Continuous intravenous infusion via a syringe pump

## Preparation of a 100 micrograms/mL solution (other strengths may be used according to local policies)

- 1. Withdraw 5 mg (10 mL) and make up to 50 mL in a syringe pump with Gluc 5%.
- 2. Cap the syringe and mix well to give a solution containing 100 micrograms/mL.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

Give by IV infusion at a rate appropriate to indication, and adjust according to clinical response and heart rate.

## Continuous intravenous infusion (large volume infusion)

#### Preparation of a 5 micrograms/mL solution (other strengths may be used according to local policies)

- 1. Remove 5 mL from a 500-mL bag of compatible infusion fluid and discard.
- Withdraw 2.5 mg (5 mL) terbutaline injection and add to the prepared infusion bag. Mix well to give a solution containing 5 micrograms/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

Give by IV infusion via a volumetric infusion device at a rate appropriate to indication, and adjust according to clinical response and heart rate.

#### **Subcutaneous injection**

### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by SC injection.

### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose and dilute to 10 mL with NaCl 0.9%.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV injection over 3-5 minutes.

# Teriparatide

#### 250 micrograms/mL solution in 3-mL pre-filled multidose pen (28 doses)

- Teriparatide is a recombinant fragment of human parathyroid hormone.
- It is used to treat osteoporosis in postmenopausal women, osteoporosis in men with *\risk* of fracture and osteoporosis associated with sustained systemic glucocorticoid therapy.

## **Pre-treatment checks**

- Avoid in pre-existing †Ca, severe renal impairment, metabolic bone diseases including hyperparathyroidism and Paget disease, skeletal malignancies or bone metastases or previous radiation therapy to the skeleton.
- Do not give if there is an unexplained *falkaline* phosphatase.
- · Caution in moderate renal impairment.
- · Patients should have calcium and vitamin D supplements prescribed if dietary intake is inadequate.
- Women of child-bearing potential should take contraceptive precautions.
- The first injection should be given in an environment where the patient can sit or lie down if orthostatic JBP occurs.

#### Biochemical and other tests

Blood pressure BMD Electrolytes: serum Ca Renal function: U, Cr, CrCl (or eGFR)

#### Dose

**Standard dose:** 20 micrograms daily by SC injection for a maximum of 24 months. The course should not be repeated during the patient's lifetime.

**Dose in renal impairment**: no dose adjustment required in mild impairment; use with caution in moderate impairment; do not give in severe renal impairment.

Dose in hepatic impairment: no data available.

## **Subcutaneous injection**

#### Preparation and administration

- 1. The injection may be given immediately after removing the pen from the refrigerator. Insulin pen needles can be used with the device.
- 2. Give by SC injection into the thigh or abdominal wall in accordance with the Forsteo User Manual.
- 3. Return the pen to the refrigerator immediately after use.

| This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations. |                                                                                                                                                                                                                                                                                                                                                                                          |                                                                                                                                       |

## Bibliography

SPC Forsteo (accessed 14 September 2009).

# **Terlipressin**

#### 1-mg dry powder vial with 5 mL solvent

#### 120 micrograms/mL (1 mg/8.5 mL) solution in 8.5-mL ampoules

- Terlipressin acetate is an inactive pro-drug that is slowly converted in the body to lypressin. It has
  the pressor activity of vasopressin and some antidiuretic activity.
- It is indicated in the treatment of bleeding from oesophageal varices and reduces the relative risk of
  mortality by about one-third.
- It has also been used to treat hepatorenal syndrome and shock (both unlicensed).
- · Doses are expressed in terms of terlipressin acetate.

#### **Pre-treatment checks**

Caution in patients with hypertension, atherosclerosis, cardiac dysrhythmias or coronary insufficiency.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Baseline plasma osmolality *or* baseline bodyweight (to enable monitoring of fluid balance) Blood pressure Electrolytes: serum Na, K

### Dose

**Acute variceal bleeding:** 2 mg by slow IV injection, followed by 1–2 mg every 4–6 hours until bleeding is controlled, up to a maximum of 72 hours.

**Hepatorenal syndrome (unlicensed):** 1 mg every 4–12 hours for 7–15 days appeared to improve renal function.

**Shock (unlicensed):** 1–2 mg by IV injection produced a progressive ↑mean arterial pressure over 10–20 minutes that was sustained for at least 5 hours, allowing reduction or cessation of noradrenaline therapy.

## Intravenous injection

#### Preparation and administration

- 1. For dry powder vials: reconstitute with the solvent supplied. Dissolve vial contents completely before withdrawing the dose.
- 2. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over 3-4 minutes.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Glypressin (accessed 3 July 2008).

# **Testosterone and esters**

Sustanon 250 (mixed testosterone esters 250 mg) oily solution in 1-mL ampoules Testosterone enantate 250 mg/mL oily solution in 1-mL ampoules Testosterone propionate 50 mg/mL oily solution in 2-mL ampoules Testosterone undecanoate 250 mg/mL oily solution in 4-mL ampoules

- Testosterone is a hormone with anabolic and androgenic properties.
- The primary use of testosterone is as replacement therapy in male hypogonadal disorders.
- The plasma half-life of testosterone is only 10–100 minutes, therefore testosterone esters are usually formulated as oily solutions for IM use to give a longer duration of action.
- Some IM testosterone preparations are licensed for use in treatment of delayed puberty in boys and also of breast cancer in women.
- · Doses below are expressed in terms of the specific ester or as millilitres of preparation.

#### **Pre-treatment checks**

- Avoid in breast cancer in men, prostate cancer, past or present liver tumour, and ↑Ca.
- A detailed medical examination should be conducted prior to treatment to exclude the risk of preexisting prostatic cancer.
- Caution in cancer patients at risk of ↑Ca.
- Caution in severe cardiac, hepatic or renal impairment or ischaemic heart disease: treatment with testosterone may cause complications characterised by oedema. Testosterone may also aggravate epilepsy and migraine.

#### Biochemical and other tests

| Blood pressure | Renal function: U, Cr, CrCl (or eGFR) |
|----------------|---------------------------------------|
| FBC            | Serum electrolytes: serum Ca          |
| LFTs           | Serum testosterone level              |
| Lipids         |                                       |

#### Dose

#### Androgen deficiency (adjust dose according to response):

- Sustanon 250: usually 1 mL by IM injection every 3 weeks.
- Testosterone propionate: usually 50 mg by IM injection 2-3 times each week.

#### Hypogonadism (adjust dose according to response):

- *Testosterone enantate*: initially 250 mg by IM injection every 2–3 weeks. Usual maintenance dose 250 mg every 3–6 weeks.
- *Testosterone undecanoate:* 1 g by IM injection every 10–14 weeks. A second injection may be given after 6 weeks depending upon testosterone levels and clinical symptoms.

#### Intramuscular injection

Contains arachis oil - should not be given in peanut allergy.

- 1. Withdraw the required dose.
- 2. Give very slowly by deep IM injection into the gluteal muscle.

# Tetracosactide (cosyntropin, tetracosactrin)

#### 250 micrograms/mL solution in 1-mL ampoules (Synacthen)

# 1mg/mL aqueous suspension (with zinc phosphate complex) in 1-mL ampoules (Synacthen Depot)

- Tetracosactide is an analogue of corticotrophin (ACTH) and is used as a diagnostic test for the investigation of adrenocortical insufficiency.
- Tetracosactide is still licensed as an alternative to corticosteroids in conditions such as Crohn disease or rheumatoid arthritis; however, its value is limited by the variable and unpredictable therapeutic response and by the waning of its effect with time.

#### **Pre-treatment checks**

- Do not give to patients who have allergic disorders, e.g. asthma.
- · Treatment with corticosteroids in the hours prior to diagnostic testing may affect the test result.

#### Biochemical and other tests

In diagnostic testing, measure plasma cortisol concentration immediately before giving the dose. In therapeutic use, measure Na and K.

#### Dose

**Short or 30-minute test:** using the 250 micrograms/mL preparation, give 250 micrograms by IM or IV injection. Measure plasma cortisol concentration immediately before the dose, and exactly 30 minutes afterwards. Adrenocortical function is considered normal if the plasma cortisol concentration rises by 200 nanomol/L (70 micrograms/L) or more.

**5-hour test:** using the 1 mg/mL preparation give 1 mg by IM injection. Measure plasma cortisol concentrations immediately before the dose, and exactly 30 minutes and 1, 2, 3, 4 and 5 hours afterwards. *Interpretation:* the 5-hour test is used where the 30-minute test is inconclusive or where it is necessary to determine the functional reserve of the adrenal cortex.

Adrenocortical function is considered normal if the plasma cortisol concentration increases 2-fold in the first hour, and continues to rise steadily. The values expected would be 600–1250 nanomol/L in the first hour, increasing slowly up to 1000–1800 nanomol/L by the fifth hour. Smaller rises in plasma cortisol may be attributable to Addison disease, secondary adrenocortical insufficiency due to a disorder of hypothalamo-pituitary function, or overdosage of corticosteroids.

**3-day test:** perform the 30-minute test just prior to giving the first day's dosing then, using the 1 mg/ mL preparation, give 1 mg by IM injection each morning for 3 days. Repeat the 30-minute test on the fourth day.

Interpretation: the 3-day test is used to differentiate between primary and secondary adrenocortical insufficiency.

A marked improvement in the second assessment suggests secondary adrenocortical insufficiency.

## Intramuscular injection

- 1. If using the 1 mg/mL preparation, shake before use to re-suspend particles.
- 2. Withdraw the required dose.
- 3. Give by IM injection.

# Intravenous injection

- 1. Using the 250 micrograms/mL preparation, withdraw the required dose (1 mL).
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration.
- 3. Give by IV injection over 2 minutes.

|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|
| Common and serious<br>undesirable effects | Immediate: Anaphylaxis and other hypersensitivity reactions (dizziness,<br>nausea, urticaria, pruritus, flushing, dyspnoea, angioedema-particularly in<br>asthmatics).<br>Injection-related: Local: Skin reactions.<br>Other: Unlikely with short-term diagnostic use; however, corticosteroid side-<br>effects (as listed under hydrocortisone) would be expected if given long term. |  |  |
| Pharmacokinetics                          | IV tetracosactide exhibits triphasic pharmacokinetics. Most of a dose is excreted<br>in the urine within 24 hours. The terminal half-life is about 3 hours.                                                                                                                                                                                                                            |  |  |
| Significant<br>interactions               | Treatment with corticosteroids in the hours prior to diagnostic testing can affect<br>the test result.<br>Other interactions are unlikely with diagnostic use. For undesirable effects<br>resulting from long-term corticosteroid use, refer to the BNF.                                                                                                                               |  |  |
| Action in case of<br>overdose             | Give supportive therapy as appropriate.                                                                                                                                                                                                                                                                                                                                                |  |  |
| Counselling                               | Make patients aware of the risk of allergic reaction and advise them to report<br>swelling in face or hands, swelling or tingling in the mouth or throat, tightness in<br>chest, trouble breathing or itching.                                                                                                                                                                         |  |  |
|                                           |                                                                                                                                                                                                                                                                                                                                                                                        |  |  |

| Risk rating:                                                                                          | GREEN | Score = 0<br>Lower-risk product. Risk-reduction strategies should be considered. |  |  |  |  |  |

# Ticarcillin with clavulanic acid

#### 1.6 g, 3.2-g dry powder vials

- Ticarcillin sodium is a carboxypenicillin. It is given in combination with the beta-lactamase inhibitor clavulanic acid to widen its spectrum of action.
- The combined preparation is used in the treatment of severe Gram-negative infections, especially
  those due to *Pseudomonas aeruginosa* including those in cystic fibrosis (respiratory tract infections),
  neutropenic sepsis, peritonitis, and septicaemia.

- Doses of ticarcillin are expressed in terms of the base:
- Ticarcillin  $1 g \equiv 1.1 g$  ticarcillin sodium.
- Ticarcillin with clavulanic acid doses are expressed below as the combined mass (mg) of the two constituents:

Ticarcillin with clavulanic acid  $3.2 \text{ g} \equiv \text{ticarcillin } 3 \text{ g}$  with clavulanic acid 200 mg.

#### **Pre-treatment checks**

Check for history of allergy/hypersensitivity to penicillins and use with caution if sensitive to other beta-lactam antibiotics.

#### Biochemical and other tests

FBC LFTs Renal function: U, Cr, CrCl (or eGFR)

#### Dose

**Standard dose:** 3.2g by IV infusion every 6–8 hours. **Severe infections:** 3.2g by IV infusion every 4 hours. **Dose in renal impairment:** adjusted according to creatinine clearance:

- CrCl >30 mL/minute: 3.2 g every 8 hours.
- CrCl 10-30 mL/minute: 1.6 g every 8 hours.
- CrCl <10 mL/minute: 1.6 g every 12 hours.

#### Intermittent intravenous infusion

#### Preparation and administration

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Reconstitute each 1.6-g vial with 5 mL WFI (use 10 mL for each 3.2-g vial) and shake well. Heat is generated as it dissolves.
- 2. Withdraw the required dose and add to a suitable volume of a compatible infusion fluid (usually 100 mL Gluc 5%). If using WFI dilute 1.6 g to 50 mL; 3.2 g to 100 mL.
- 3. The solution should be clear and a pale straw colour. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 30-40 minutes.

#### Additional information (continued)

Counselling Women taking the combined contraceptive pill should be should be advised to take additional precautions during and for 7 days after the course.

#### Risk rating: AMBER

Score = 3 Moderate-risk product: Risk-reduction strategies are recommended.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

## **Bibliography**

SPC Timentin 0.8 G, 1.6 G, 3.2 G (accessed 3 April 2009).

# **Tigecycline**

#### 50-mg dry powder vials

- Tigecycline, a synthetic derivative of minocycline, is a glycylcycline antibacterial structurally similar to tetracyclines.
- It is active against a broad range of Gram-positive and Gram-negative bacteria, including tetracycline-resistant organisms and some anaerobic organisms.
- It is used for the treatment of complicated skin and soft-tissue infections or complicated intraabdominal infections caused by susceptible organisms.

### **Pre-treatment checks**

- Do not use if the patient is hypersensitive to other tetracyclines or in pregnancy.
- Caution in cholestasis.

#### Biochemical tests

LFTs

Prothrombin time and activated partial thromboplastin time (APTT) – especially if the patient is taking anticoagulants.

#### Dose

**Standard dose:** initially 100 mg, followed by 50 mg every 12 hours for 5–14 days (dependent on severity, site of infection and the patient's clinical response).

**Dose in hepatic impairment:** use with caution in severe hepatic impairment (Child–Pugh C), reduce to 25 mg every 12 hours after the 100-mg loading dose.

# Intermittent intravenous infusion

- 1. Reconstitute each 50-mg vial with 5.3 mL of NaCl 0.9 % or Gluc 5%. Gently swirl until contents dissolve to produce a solution containing 10 mg/mL.
- 2. Withdraw the required dose and add to a 100 mL Gluc 5% or NaCl 0.9%.
- 3. The solution should be clear and yellow to orange in colour. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 30-60 minutes.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Tygacil 50 mg powder for solution for infusion (accessed 3 April 2009).

# Tinzaparin sodium

 $10\,000$  units/mL pre-filled syringes: 2500 units/0.25 mL, 3500 units/0.35 mL, 4500 units/  $0.45\,mL$ 

#### 10000 units/mL solution in 2-mL multidose vials

20000 units/mL pre-filled syringes: 10000 units/0.5 mL, 14000 units/0.7 mL, 18000 units/0.9 mL

#### 20000 units/mL solution in 2-mL multidose vials

- Tinzaparin is a low-molecular-weight heparin (LMWH).
- It is used in the treatment of venous thromboembolism (VTE) i.e. pulmonary embolism (PE) and deep vein thrombosis (DVT).
- It is used for prophylaxis of VTE in surgical patients and to prevent thrombus formation in the extracorporeal circulation during haemodialysis.
- Doses are expressed in terms of international anti-Factor Xa activity units: Tinzaparin sodium  $1 \text{ mg} \cong 70-120$  units of anti-Factor Xa activity.

## **Pre-treatment checks**

- Avoid in acute bacterial endocarditis, major bleeding or high risk of uncontrolled haemorrhage including recent haemorrhagic stroke.
- Tinzaparin in treatment dosage is contraindicated in patients undergoing locoregional anaesthesia in elective surgical procedures.
- Placement or removal of a spinal/epidural catheter should be delayed for 10–12 hours after administration of prophylactic doses, whereas patients receiving treatment doses require a 24hour delay. Subsequent dosing should be given no sooner than 4 hours after catheter removal.
- Caution with other drugs affecting haemostasis, such as aspirin or clopidogrel.
- Use with extreme caution in patients with a history of heparin-induced thrombocytopenia.

#### *Biochemical and other tests (not all are necessary in an emergency situation)*

Bodyweight (in certain indications) Electrolytes: serum K INR (in certain indications) Platelet count Renal function: U, Cr, CrCl (eGFR)

## Dose

#### Prophylaxis

**General surgery with low to moderate risk of VTE:** 3500 units by SC injection 2 hours before surgery and then once daily until the patient is mobile.

**General surgery or orthopaedic with high risk of VTE:** 4500 units by SC injection 12 hours before surgery followed by a once-daily dose until the patient is mobile, or 50 units/kg bodyweight by SC injection 2 hours before surgery followed by a once-daily dose until the patient is mobile.

**Prevention of extracorporeal thrombus formation during haemodialysis:** see product literature.

#### Treatment

**Treatment of VTE:** 175 units/kg bodyweight by SC injection once daily as indicated in Table T2 below (doses have been rounded to facilitate administration). Treat for at least 6 days and until INR > 2.

Dose in renal impairment: adjusted according to creatinine clearance:1

- CrCl >20-50 mL/minute: dose as in normal renal function.
- CrCl 10–20 mL/minute: dose as in normal renal function for prophylaxis only. For treatment doses either monitor anti-Factor Xa levels or use unfractionated heparin.
- CrCl <10 mL/minute: dose as in normal renal function for prophylaxis only. For treatment doses either monitor anti-Factor Xa levels or use unfractionated heparin.

Dose in hepatic impairment: the manufacturer advises avoid in severe hepatic impairment.

## **Subcutaneous injection**

#### Preparation and administration

- 1. Select the correct pre-filled syringe. Pre-filled syringes are ready for immediate use; do not expel the air bubble. If necessary expel excess tinzaparin to give the required dose.
- 2. If using multidose vials, withdraw the required dose using a needle suitable for SC administration.
- 3. The patient should be seated or lying down.
- 4. Pinch up a skin fold on the abdominal wall between the thumb and forefinger and hold throughout the injection.
- Give by deep SC injection into the thick part of the skin fold at right angles to the skin. Do not rub the injection site after administration. Alternate doses between the right and left sides.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

 Table T2
 Tinzaparin treatment of VTE

# Tirofiban

# 50 micrograms/mL solution in 250-mL infusion bags; 250 micrograms/mL solution in 50-mL vials

- Tirofiban hydrochloride is an antiplatelet drug that reversibly inhibits binding of fibrinogen to the glycoprotein IIb/IIIa receptors of platelets.
- It is given with heparin and aspirin for the management of unstable angina, both in patients managed medically and in those undergoing PCI.
- Doses are expressed in terms of the base: Tirofiban 50 micrograms ≅ 55 micrograms tirofiban hydrochloride.

## **Pre-treatment checks**

- Avoid in abnormal bleeding within 30 days, stroke within 30 days or any history of haemorrhagic stroke, intracranial disease (aneurysm, neoplasm or arteriovenous malformation), severe †BP, haemorrhagic diathesis, †PT or INR, thrombocytopenia; and breast feeding.
- Caution in major surgery or severe trauma within 3 months (avoid if within 6 weeks); traumatic or
  protracted cardiopulmonary resuscitation, organ biopsy or lithotripsy within the previous 2 weeks;
  risk of bleeding including active peptic ulcer within 3 months; acute pericarditis, aortic dissection,
  haemorrhagic retinopathy, vasculitis, haematuria, faecal occult blood; severe heart failure, cardiogenic shock, anaemia; concomitant drugs that ↑risk of bleeding (including within 48 hours of
  thrombolytic administration).
- Discontinue if thrombolytic therapy, intra-aortic balloon pump or emergency cardiac surgery is necessary.
- · Caution in hepatic and renal impairment, and in pregnancy.
- The number of vascular punctures and IM injections should be minimised during the treatment.
- IV access should be obtained only at compressible sites of the body.
- All vascular puncture sites should be documented and closely monitored (caution if there is puncture of non-compressible vessel within 24 hours).
- The use of urinary catheters, nasotracheal intubation and nasogastric tubes should be critically considered before commencing therapy.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| APTT           | FBC (including platelets, Hb and haematocrit) |
|----------------|-----------------------------------------------|
| Blood pressure | LFTs (avoid in severe impairment)             |
| Bodyweight     | Renal function: U, Cr, CrCl (or eGFR)         |

#### Dose

**Standard dose:** initially 0.4 microgram/kg/minute by IV infusion for 30 minutes, followed by a maintenance dose of 0.1 microgram/kg/minute by IV infusion. See Table T3 below. Infusion should ideally be started within 12 hours of the last anginal episode and continued for at least 48 hours. **Concomitant therapy with unfractionated heparin:** 5000 units by IV injection at the start of

tirofiban therapy, followed by 1000 units/hour by IV infusion, titrated to maintain APTT ratio at about 2.

- *Coronary angiography:* the infusion (and heparin) may be continued during the procedure and should be maintained for 12–24 hours after angioplasty or atherectomy.
- *If no coronary intervention procedure is planned:* discontinue infusion once the patient is clinically stable. Maximum duration of treatment should be no more than 108 hours.
- If PTCA is required: heparin should be stopped after PTCA, and the sheaths should be withdrawn
  once coagulation has returned to normal, i.e. when the ACT <180 seconds (usually 2–6 hours after
  discontinuation of heparin).</li>

Dose in renal impairment: adjusted according to creatinine clearance:

- CrCl >30-50 mL/minute: dose as in normal renal function.
- CrCl 10–30 mL/minute: give 50% of the standard dose.
- CrCl <10 mL/minute: give 50% of the standard dose.</li>

Dose in hepatic impairment: avoid in severe impairment.

# Continuous intravenous infusion using pre-prepared solution

Preparation and administration

NB: The loading infusion is given over 30 minutes and then the rate is reduced.

- 1. The 50 micrograms/mL strength in the infusion bag is pre-prepared for use.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present. Some opacity of the plastic is normal.
- 3. Remove the plastic protector from the outlet port at the bottom of the container and attach the giving set.
- 4. Give by IV infusion using a volumetric infusion device at the appropriate rate (see Table T3 below). Ensure that the initial loading infusion rate does not continue for longer than 30 minutes.

#### Continuous intravenous infusion using concentrate

#### Preparation and administration

NB: The loading infusion is given over 30 minutes and then the rate is reduced.

- 1. Withdraw 50 mL from a 250-mL infusion bag of NaCl 0.9% or Gluc 5% and discard.
- Using the 250 micrograms/mL strength, withdraw 50 mL tirofiban from the 50-mL vial and add to the prepared infusion bag.
- 3. Mix well to give a solution containing 50 micrograms/mL.
- 4. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by IV infusion using a volumetric infusion device at the appropriate rate (see Table T3 below). Ensure that the initial loading infusion rate does not continue for longer than 30 minutes.

 Table T3
 Loading and maintenance infusion rates using a 50 micrograms/mL solution

# Tobramycin

#### 40 mg/mL solution in 1-mL, 2-mL and 6-mL ampoules

- · Tobramycin sulfate is an aminoglycoside antibiotic.
- It has actions and uses similar to gentamicin and is used particularly in the treatment of pseudomonal infections.
- Dose is calculated on the basis of renal function (as it is almost completely renally excreted) and bodyweight. However, tobramycin is not lipophilic so the dose should be based on ideal bodyweight (IBW) rather than actual body weight (ABW). Some authorities recommend using a 'dosing weight' calculated by adding IBW to 40% of the difference between ABW and IBW. Whichever method is employed, it is important to check these criteria to avoid overdosing, e.g. in short, obese individuals with impaired renal function.
- Doses are expressed in terms of the base: Tobramycin  $40 \text{ mg} \equiv 60 \text{ mg}$  of tobramycin sulfate.

#### **Pre-treatment checks**

- · Do not give in myasthenia gravis.
- Ensure good hydration status (dehydration ↑risk of toxicity).

#### Biochemical and other tests

 Baseline check of auditory and vestibular
 Electrolytes: serum Na, K (Mg, Ca if long term)

 function
 FBC

 Bodyweight and possibly height if patient over Renal function: U, Cr, Cr Cl (or eGFR)

 weight
 Kernel function: U, Cr, Cr Cl (or eGFR)

#### Dose

To avoid excessive dosing, doses should be calculated on the basis of ideal bodyweight (IBW) in obese patients. (See Appendix 10.)

**Serious infections:** give every 8 hours by IM or IV injection or IV infusion to provide a total daily dose of 3 mg/kg/day.

**Life-threatening infections:** give every 6–8 hours by IM or IV injection or IV infusion to provide a total daily dose of 5 mg/kg/day. This should be reduced to 3 mg/kg/day as soon as clinically indicated. **Cystic fibrosis:** give every 6–8 hours by IM or IV injection or IV infusion to provide a total daily dose of up to 8–10 mg/kg/day if required.

Urinary tract infection: 2-3 mg/kg daily by IM injection.

**Dose in renal impairment:** a loading dose of 1 mg/kg is given then doses are adjusted according to creatinine clearance and IBW. Either the dose interval can be adjusted (Table T4) or a reduced dose may be given every 8 hours (Table T5).

Table T4 Dose frequency adjustment of tobramycin in renal impairment

| Normal dose at<br>prolonged interval: | IBW 50–60 kg: dose is 60 mg<br>IBW 60–80 kg: dose is 80 mg |
|---------------------------------------|------------------------------------------------------------|
| Creatinine clearance<br>(mL/minute)   | Dose frequency                                             |
| >70                                   | Every 8 hours                                              |
| 40 to 69                              | Every 12 hours                                             |
| 20 to 39                              | Every 18 hours                                             |
| 10 to 19                              | Every 24 hours                                             |
| 5 to 9                                | Every 36 hours                                             |
| <4                                    | Every 48 hours (when dialysis not performed)               |

| Table T5 | Dose ad | justment | of tobram | ycin in | renal in | npairment |
|----------|---------|----------|-----------|---------|----------|-----------|
|----------|---------|----------|-----------|---------|----------|-----------|

| Creatinine clearance | Adjusted dose (mg) at 8-hourly intervals |              |  |  |
|----------------------|------------------------------------------|--------------|--|--|
| (mL/minufe)          | IBW 50-60 kg                             | IBW 60-80 kg |  |  |
| >70                  | 60                                       | 80           |  |  |
| 40 to 69             | 30-60                                    | 50-80        |  |  |
| 20 to 39             | 20-25                                    | 30-45        |  |  |
| 10 to 19             | 10-18                                    | 15-24        |  |  |
| 5 to 9               | 5-9                                      | 7-12         |  |  |
| <4                   | 2.5-4.5                                  | 3.5-6        |  |  |

# Intramuscular injection

- 1. Withdraw the required dose.
- 2. Give by deep IM injection.

## Intermittent intravenous infusion

Preparation and administration

If used in combination with a penicillin or cephalosporin, preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Withdraw the required dose and add to 50-100 mL of a NaCl 0.9% or Gluc 5%.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 20-60 minutes.

#### Intravenous injection

Preparation and administration

If used in combination with a penicillin or cephalosporin, preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Withdraw the required dose.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 3–5 minutes. May be diluted to 10 mL with NaCl 0.9% or Gluc 5% to facilitate slow administration.

Moderate-risk product: Risk-reduction strategies are recommended.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Tobramycin 40 mg/mL injection, Hospira UK Ltd (accessed 5 March 2010).

# Tramadol hydrochloride

#### 50 mg/mL solution in 2-mL ampoules

- Tramadol hydrochloride is an opioid analgesic that also enhances serotonergic and adrenergic pathways, adding to its analgesic effect.
- It is used to treat and prevent moderate to severe pain. It has fewer opioid side-effects than other opioids and a lower potential for addiction.
- It is sometimes used as an alternative to pethidine for patient-controlled analgesia in morphineintolerant patients.
- Tramadol may precipitate serotonin syndrome when used with other serotonergic drugs.

## **Pre-treatment checks**

- Do not use in uncontrolled epilepsy; acute porphyria.
- Caution in impaired consciousness and excessive bronchial secretions.
- · Not suitable as a substitute in opioid-dependent patients.

#### Biochemical and other tests

LFTs Renal function: U, Cr, CrCl (or eGFR)

### Dose

Pain: 50-100 mg by IM or IV injection every 4-6 hours.

**Postoperative pain:** 100 mg initially then 50 mg every 10–20 minutes when needed during the first hour (to maximum total 250 mg including initial dose), then 50–100 mg every 4–6 hours (to maximum 600 mg daily).

Dose in renal impairment: doses should be adjusted according to creatinine clearance:1

- CrCl 10-20 mL/minute: 50-100 mg every 8-12 hours.
- CrCl <10 mL/minute: 50 mg every 8–12 hours.

Dose in severe hepatic impairment: dose interval should be 12-hourly (or avoid tramadol).

## Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by deep IM injection.
- 3. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over at least 2-3 minutes (rapid IV administration *†*risk of adverse effects).
- 4. Close monitoring of respiratory rate and is consciousness recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

# Patient-controlled analgesia<sup>2</sup>

Strength used may vary depending on local policies.

#### Preparation and administration

- 1. Make 500 mg (10 mL) tramadol up to 50 mL with NaCl 0.9% in a PCA syringe to give a solution containing 10 mg/mL.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- The usual setting for the PCA device is to deliver a 5-mg bolus with a 5-minute lock-out period. Lower doses are used in patients with renal failure.

#### **Continuous or intermittent intravenous infusion**

- 1. Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually NaCl 0.9% or Gluc 5%).
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by continuous or intermittent IV infusion at a suitable rate via a volumetric infusion device.
- 4. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

| Stability after<br>preparation | From a microbiological point of view, should be used immediately; however, prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours. |  |

#### Monitoring

Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

# **Tranexamic acid**

#### 100 mg/mL solution in 5-mL ampoules

- Tranexamic acid is an antifibrinolytic agent that primarily acts by blocking the binding of plasminogen and plasmin to fibrin, inhibiting the breakdown of fibrin clots.
- It is used to prevent or treat bleeding associated with excessive fibrin breakdown, e.g. in prostatectomy, bladder surgery and dental surgery in patients with haemophilia; it is also used in the management of menorrhagia.
- · It is used in haemorrhagic complications associated with thrombolytic therapy.
- It is also licensed for use in haemorrhage associated with DIC where activation of the fibrinolytic system predominates (see Pre-treatment checks below). It should not be used if activation of the coagulation system predominates.

#### **Pre-treatment checks**

- Do not use if there is a history of thromboembolic disease.
- Caution in haematuria (clots formed in the renal system can lead to obstructive renal impairment).

#### 838 | Tranexamic acid

In DIC confirm predominant activation of the fibrinolytic system by checking haematological
profile (prolonged prothrombin time; reduced euglobulin clot lysis time; reduced plasma fibrinogen, factor V, factor VIII, plasminogen and alpha-2 macroglobulin levels; normal plasma P and
P complex levels; 
plasma levels of fibrinogen degradation products; normal platelet count)
assuming that the underlying disease state has not modified the elements of this profile.

Biochemical and other tests (not all are necessary in an emergency situation

Renal function: U, Cr, CrCl (or eGFR)

#### Dose

**Local fibrinolysis**: 500 mg–1 g by IV injection three times daily. If IV treatment is likely to be required for more than 3 days, 25–50 mg/kg/day may be given by continuous IV infusion.

**Disseminated intravascular coagulation with predominant activation of fibrinolytic system:** 1 g by IV injection is usually sufficient to control bleeding, and maintain a reduced fibrinolytic level of activity for around 4 hours in normal renal function. Anticoagulation with heparin should be commenced to prevent further deposition of fibrin.

Neutralisation of thrombolytic therapy: 10 mg/kg bodyweight by slow IV injection.

Dose in renal impairment: adjusted according to creatinine clearance:<sup>1</sup>

- CrCl >20-50 mL/minute: 10 mg/kg every 12 hours.
- CrCl 10-20 mL/minute: 10 mg/kg every 12-24 hours.
- CrCl <10 mL/minute: 5 mg/kg every 12–24 hours.

#### Intravenous injection (preferred method)

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection at a rate of 1 mL/minute (100 mg/minute).

# Continuous intravenous infusion (longer duration of therapy)

- 1. Withdraw the required dose and add to a convenient volume of compatible infusion fluid. Mix well.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion at a dose of 25–50 mg/kg/day. Prepare a new infusion bag every 24 hours as required.

# Bibliography

SPC Cyklokapron injection (accessed 14 May 2009).

# Triamcinolone

# 40 mg/mL aqueous suspension in 1-ml vials; 1-mL and 2-mL pre-filled syringes 10 mg/mL aqueous suspension in 1-mL ampoules and 5-mL vials

- Triamcinolone acetonide is a corticosteroid with mainly glucocorticoid activity.
- It is used in the treatment of conditions for which systemic corticosteroid therapy is indicated (except
  adrenal-deficiency states). Deep IM injections have a depot effect and may provide cover for several weeks.
- It may also be given by intra-articular, intrasynovial or intralesional injection for various inflammatory conditions.
- · Doses for injection are expressed triamcinolone acetonide.

#### **Pre-treatment checks**

- · Avoid where systemic infection is present (unless specific therapy given).
- · Avoid live virus vaccines in those receiving immunosuppressive doses.
- May activate or exacerbate amoebiasis or strongyloidiasis (exclude before initiating a corticosteroid in those at risk or with suggestive symptoms). Fungal or viral ocular infections may also be exacerbated.
- Caution in patients predisposed to psychiatric reactions, including those who have previously suffered corticosteroid-induced psychosis, or who have a personal or family history of psychiatric disorders.

Intra-articular:

- Do not inject into unstable joints.
- · Do not give in the presence of active infection in or near joints.

#### Dose

**Intramuscular:** initially 40 mg repeated at intervals according to patient response, maximum single dose 100 mg. Patients with hay fever may gain remission of symptoms lasting throughout the season after a single 40–100-mg dose.

**Intra-articular or intrasynovial or intradermal injection:** large joints: up to 40 mg; small joints: 2.5–10 mg; multiple joint involvement: up to a total of 80 mg; intradermal: 2–3 mg depending on the size of the lesion and using the 10 mg/mL strength. No more than 5 mg should be injected at any one site. If several sites are injected the total dose should not exceed 30 mg and multiple sites should be 1 cm or more apart. The injection may be repeated at 1- to 2-week intervals.

#### Intramuscular injection

#### Preparation and administration

- 1. Shake vial well before withdrawing medication. If clumping occurs, do not use.
- 2. Withdraw the required dose.
- Give by IM injection deep into the upper outer quadrant of the gluteal muscle (avoid the deltoid). Use alternate sides for subsequent injections.

#### Other routes

- 1. Shake vial well before withdrawing the medication. If clumping occurs, do not use.
- 2. Withdraw the required dose.
- Remove the IM needle that comes with the pre-filled syringe and replace with a needle appropriate to the planned route.
- 4. Inject into the affected area.
- In tenosynovitis care should be taken to inject into the tendon sheath rather than into the substance of the tendon. For short tendons the 10 mg/mL strength should be used.
- After intra-articular injections treatment failure is usually the result of not entering the joint space.

# Technical information Incompatible with Not relevant Compatible with Not relevant pH Not relevant Sodium content Negligible Excipients Both preparations contain benzyl alcohol. Storage Store below 25°C in an upright position in original packaging. Do not freeze.

# Monitoring (dependent on dose and site of injection)

| Measure                          | Frequency                                                     | Rationale                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

# **Triptorelin**

#### 3-mg and 11.25-mg (Decapeptyl SR); 3.75-mg (Gonapeptyl Depot) dry powder preparations with solvent

- Triptorelin acetate is an analogue of gonadorelin.
- It is used for the suppression of testosterone in the treatment of prostate cancer as an alternative to surgical castration.
- It is also licensed for use in the treatment of endometriosis, female infertility and uterine fibroids and in precocious puberty.
- Doses are expressed in terms of the base: Triptorelin 1 mg ≡ 1.05 mg triptorelin acetate.

## **Pre-treatment checks**

Caution in osteoporosis (or those at risk: i.e. chronic alcohol and/or tobacco use, strong family history of osteoporosis, or chronic use of drugs that can  $\downarrow$ BMD, e.g. anticonvulsants or corticosteroids).

#### Biochemical and other tests

Blood pressure Pregnancy test (in endometriosis) Testosterone level (in prostate cancer) Consider BMD if treatment is to be prolonged

#### Dose

#### **Prostate cancer:**

- Decapeptyl SR: 3 mg by IM injection every 4 weeks, or 11.25 mg by IM injection every 12 weeks.
- *Gonapeptyl Depot:* 3.75 mg by SC or IM injection every 4 weeks.

An anti-androgen agent may be given for 3 days before until 2–3 weeks after commencement of either therapy to *\\_*risk of disease flare, e.g. cyproterone acetate 100 mg three times daily.

Endometriosis: initiate treatment in the first 5 days of the menstrual cycle.

- Decapeptyl SR: 3 mg by IM injection every 4 weeks, or 11.25 mg by IM injection every 12 weeks for a maximum of 6 months.
- Gonapeptyl Depot: 3.75 mg by SC or IM injection every 4 weeks for a maximum of 6 months.

Uterine fibroids: initiate treatment in the first 5 days of the menstrual cycle.

- Decapeptyl SR: 3 mg by IM injection every 4 weeks for a minimum of 3 months and a maximum of 6 months.
- Gonapeptyl Depot: 3.75 mg by SC or IM injection every 4 weeks for a maximum of 6 months.

# Intramuscular injection (Decapeptyl SR)

- 1. Draw the solvent provided into the syringe using the pink needle and transfer into the powder vial. Do not remove the needle from the vial.
- 2. Shake the vial gently to produce a homogeneous mixture (make sure any clumps are dispersed) then draw the mixture back into the syringe without inverting the vial. The small amount of suspension left in the vial should be discarded as the vials contain an overage to allow the prescribed dose to be given.
- 3. Attach the green needle provided and give by IM injection into the gluteal muscle. Rotate injection sites for subsequent injections.

# Intramuscular or subcutaneous injection (Gonapeptyl Depot)

- 1. Remove the cap from the syringe containing the powder, keeping it upright to prevent spillage.
- 2. Without removing the connector from the packaging, screw the syringe containing the powder onto the connector and then remove it from the package.
- 3. Screw the syringe containing the solvent tightly onto the free end of the connector and empty the solvent into the syringe with the powder.
- 4. Shoot it back and forth between the two syringes (the first 2–3 times without pushing the injection rod all the way in). Repeat this about 10 times or until the suspension is homogeneous and milky.
- 5. If foam is produced, dissolve it or remove it from the syringe before giving the injection.
- 6. Attach the injection needle on to the syringe and give by SC injection (abdomen, buttock or thigh) or by deep IM injection. Rotate injection sites for subsequent injections.

| Common and serious<br>undesirable effects | Injection-related: Transient pain, redness or local inflammation at the injection<br>site.<br>Other: Hypersensitivity reactions; depressive mood; irritation; nausea; myalgia;<br>arthralgia; tiredness; sleep disturbances; gynaecomastia; headache;<br>perspiration.<br>In men: Hot flushes, ↓libido and impotence, ↑bone pain, worsening of<br>genitourinary obstruction symptoms (haematuria, urinary disorders) and/or<br>worsening of neurological signs of vertebral metastases (back pain, weakness<br>or paraesthesia of the lower limbs). These often occur from the initial and<br>transient increase in plasma testosterone and usually disappear in 1-2 weeks.<br>In women: Hot flushes, sweating, sleep disturbances, headache, mood<br>changes, vaginal dryness, dyspareunia, ↓libido, symptoms of endometriosis<br>(pelvic pain, dysmenorrhoea). These often occur from the initial and transient<br>increase in plasma estradiol levels and usually disappear in 1-2 weeks. |  |
| Pharmacokinetics                          | Elimination half-life is 3-7.5 hours.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |  |
| Significant<br>interactions               | No significant interactions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |  |
| Action in case of<br>overdose             | There is no specific antidote and treatment should be symptomatic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |
| Counselling                               | In women a non-hormonal method of contraception should be used throughout treatment and until resumption of menstruation or until another contraceptive method has been established (ovarian function resumes after withdrawal of treatment and ovulation occurs on average 58 days after the last injection, with menstrual bleeding resuming 7-12 weeks after the final injection). Non-hormonal, barrier methods of contraception should be used during the entire treatment period.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |  |

| Risk rating: GREEN | Score = 1<br>Lower-risk product: Risk-reduction strategies should be considered. |  |

## Urokinase

## 10 000-unit, 25 000-unit, 100 000-unit dry powder vials (other strengths are available on 'special order')

- · Urokinase is a plasminogen activator enzyme produced by the kidneys. It has thrombolytic activity.
- It is licensed for the dissolution of fibrin clots in intravascular cannulas, and also for the treatment of DVT, PE and peripheral vascular occlusion.

### **Pre-treatment checks**

- Caution when risk of haemorrhage is increased, e.g. surgery, cerebrovascular bleeding, severe *\partial BP*, peptic ulcer disease/risk of GI bleeding. Also in pregnancy and the immediate postpartum period, severe hepatic or renal insufficiency unless the patient is receiving renal replacement therapy.
- · Caution in patients who have had recent repeated intravascular puncture.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Bodyweight (in certain indications) LFTs – do not give in severe disease

#### Dose

**Cannula occlusion:** 5000–25 000 units (see below for method). Alternatively, for cannulas at risk of fibrin occlusion, an infusion of up to 250 000 units may be given through the cannula.

DVT/PE loading dose: 4400 units/kg by IV infusion over 10 minutes.

DVT/PE maintenance: 4400 units/kg/hour by IV infusion for 12-24 hours (12 hours for PE).

**PE via pulmonary artery:** 15 000 units/kg by injection into the pulmonary artery repeated up to three times in 24 hours. The dose is adjusted depending on the plasma fibrinogen concentration produced by the previous injection.

Peripheral vascular occlusion: see product literature for details.

### **Clearance of occluded intravenous cannulas**

### Preparation and administration

- 1. Check that you have selected the correct strength of vial.
- Determine the volume of NaCl 0.9% required to fill the lumen and use this to dissolve the vial contents (as little as 0.5 mL is sufficient).
- Withdraw the required quantity of urokinase and mix with a further volume of NaCl 0.9% if necessary to make up to the required volume.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Aspirate the cannula then instil the solution and cap for 20–60 minutes (up to 4 hours may be necessary in some cases).
- 6. Aspirate the cannula and repeat if necessary.

### **Cannula infusion**

#### Preparation and administration

Check that you have selected the correct strength of vial(s). Urokinase is incompatible with Gluc solutions.

- 1. Reconstitute each vial with 2 mL NaCl 0.9% and shake gently to dissolve the powder.
- Withdraw the required quantity of urokinase and add to a suitable volume of NaCl 0.9% to give a solution containing 1000–2500 units/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Infuse through the affected cannula over 90-180 minutes.

### Intravenous infusion (loading dose)

Preparation and administration

Check that you have selected the correct strength of vial(s). Urokinase is incompatible with Gluc solutions.

- 1. Reconstitute each vial with 2 mL NaCl 0.9% and shake gently to dissolve the powder.
- 2. Withdraw the required dose and make up to a final volume of 15 mL with NaCl 0.9%.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 10 minutes.

### Continuous intravenous infusion via a syringe pump

#### Preparation and administration

Check that you have selected the correct strength of vial(s). Urokinase is incompatible with Gluc solutions.

- 1. Reconstitute each vial with 2 mL NaCl 0.9% and shake gently to dissolve the powder.
- 3. Cap the syringe and mix well.
- 4. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by IV infusion at a rate appropriate to the indication.

### Intra-arterial use

Preparation

As for IV use.

### Risk rating: **RED**

Score = 7

High-risk product. Risk-reduction strategies are required to minimise these risks.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

### Bibliography

SPC Syner-KINASE 10,000 IU, 25,000 IU, 100,000 IU, 250,000 IU, 500,000 IU, 1,000,000 IU (accessed 2 April 2010).

## Vancomycin

### 500-mg, 1-g dry powder vials

- · Vancomycin hydrochloride is a glycopeptide antibiotic.
- It is used IV in potentially life-threatening infections due to susceptible Gram-positive organisms including MRSA.
- Oral vancomycin is indicated for severe cases of antibiotic-associated pseudomembranous colitis (usually involving *Clostridium difficile*) and staphylococcal enterocolitis. The injection form may be given orally if necessary.
- Since it is not absorbed from the GI tract, vancomycin is not effective by the oral route for other types of infection.
- Vancomycin is **not** intended for IM administration.
- Doses are expressed in terms of the base: Vancomycin 1 g (1000000 IU)  $\equiv$  1.03 g vancomycin hydrochloride.

### **Pre-treatment checks**

Caution in hypersensitivity to teicoplanin

#### Biochemical and other tests

Auditory function (especially if >60 years) FBC Renal function: U, Cr, CrCl (or eGFR)

### Dose

Initial IV dose: 1 g by IV infusion every 12 hours.

Initial IV dose in elderly patients: 500 mg every 12 hours, or 1 g every 24 hours.

**Antibiotic-associated pseudomembranous colitis (oral):** 125 mg orally every 6 hours (up to 2 g/day in severe cases) usually for 7–10 days.

**Dose in renal impairment**: initiate IV dose according to creatinine clearance then adjust according to serum vancomycin level (see *The Renal Drug Handbook* for further detail and other strategies):<sup>1</sup>

- CrCl >20-50 mL/minute: 500 mg-1 g every 12-24 hours.
- CrCl 10-20 mL/minute: 500 mg-1 g every 24-48 hours.
- CrCl <10 mL/minute: 500 mg-1g every 48-96 hours.
- Oral dose is as in normal renal function

### Intermittent intravenous infusion (preferred method)

### Preparation and administration

- 1. Reconstitute each 500-mg vial with 10 mL WFI (use 20 mL for each 1-g vial) to give a solution containing 50 mg/mL.
- 2. Withdraw the required dose and add to a suitable volume of compatible infusion fluid. Each 500 mg must be added to a minimum of 100 mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over a minimum of 60 minutes at a maximum rate of 10 mg/minute. To reduce the risk of 'red man' syndrome (see below) a 1-g dose is usually given over 2 hours.

Fluid restriction: the maximum concentration is 10 mg/mL, but *†risk* of infusion-related effects.

## Continuous intravenous infusion (use only if intermittent technique is not feasible)

### Preparation and administration

- 1. Reconstitute each 500-mg vial with 10 mL WFI (use 20 mL for each 1-g vial) to give a solution containing 50 mg/mL.
- Withdraw the total daily dose and add to a sufficiently large volume of compatible infusion fluid. Mix well.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give the total daily dose by IV infusion over 24 hours.

### Oral

- 1. Reconstitute each 500-mg vial with 10 mL WFI (use 20 mL for each 1-g vial) to give a solution containing 50 mg/mL.
- Withdraw the required dose and dilute in 30 mL of water. May be mixed with common cordials immediately before administration to mask the taste.
- 3. Give to the patient to drink or administer via NG tube.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

## Vasopressin (antidiuretic hormone, ADH)

### 20 argipressin pressor units/mL (400 micrograms/mL) solution in 1-mL ampoules

- Vasopressin has a direct antidiuretic action on the kidney, increasing tubular reabsorption of
  water. It also constricts peripheral blood vessels and causes contraction of the smooth muscle of
  the intestine, gall bladder and urinary bladder.
- It may be used in the short-term treatment of pituitary (rather than nephrogenic) diabetes insipidus.
- It may be used to control variceal bleeding in portal hypertension prior to more definitive treatment. However, terlipressin and octreotide are now preferred treatments.
- Argipressin is a form of vasopressin obtained from most mammals including humans. Doses are usually expressed in terms of pressor units:

Vasopressin 100 micrograms  $\equiv$  5 argipressin pressor units.

### **Pre-treatment checks**

- · Do not give in chronic nephritis with nitrogen retention.
- Caution in patients with hypertension and also in coronary artery disease (even small doses may precipitate anginal pain).
- If used in peripheral vascular disease the skin should be observed for signs of ischaemia.
- Caution in conditions which may be aggravated by fluid retention, e.g. epilepsy, migraine, asthma, heart failure.

### Biochemical and other tests

Baseline plasma osmolality *or* baseline bodyweight (to enable monitoring of fluid balance) Electrolytes: Serum Na, K

### Dose

**Diabetes insipidus:** 0.25–1 mL (5–20 units) by SC or IM injection every 4 hours. Tailor dose to allow a slight diuresis every 24 hours to avoid water intoxication.

Variceal bleeding: for the initial control of variceal bleeding give 1 mL (20 units) by IV infusion.

### **Subcutaneous injection**

Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by SC injection.

### Intramuscular injection

### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

### Intravenous infusion

- 1. Withdraw the required dose and add to 100 mL Gluc 5%.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 15 minutes. Monitor closely for signs of extravasation.

## Verapamil hydrochloride

### 2.5 mg/mL solution in 2-mL ampoules

- Verapamil hydrochloride is a calcium channel blocker and a class IV antiarrhythmic agent. It slows
  conduction through the AV node, thus reducing heart rate and cardiac output.
- It is indicated for the treatment of paroxysmal SVT and to \ventricular rate in atrial flutter/AF.

### **Pre-treatment checks**

• Do not give in cardiogenic shock, sinoatrial block, and uncompensated heart failure.

### 856 | Verapamil hydrochloride

- Avoid in acute MI complicated by \u03c4pulse, marked \u03c4BP or LVF, in second- or third-degree AV block (except in patients with a functioning artificial ventricular pacemaker), and in sick sinus syndrome (except in patients with a functioning artificial ventricular pacemaker).
- Do not give in ↓pulse (<50 beats/minute) or ↓BP (<90 mmHg systolic).
- Avoid with concurrent or recent administration of an IV beta-blocker.
- Avoid if possible in patients with atrial flutter/AF in the presence of an accessory pathway (e.g. Wolff–Parkinson–White syndrome): may \conduction across the anomalous pathway, which may precipitate severe VT.
- Caution in first-degree AV block.

### Biochemical and other tests (not all are necessary in an emergency situation)

Electrolytes: serum Na, K, Ca, Mg

### Dose

Supraventricular arrhythmias: 5–10 mg by slow IV injection.

**Paroxysmal tachyarrhythmias**: 5–10 mg by slow IV injection, followed by a further 5 mg after 5–10 minutes if required.

### Intravenous injection

- 1. Withdraw the required dose.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration.
- 3. Give by slow IV injection over at least 2 minutes (3 minutes in elderly patients).

|                    |                                                                                  |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

### **Bibliography**

SPC Securon IV (accessed 29 April 2009).

## Voriconazole

### 200-mg dry powder vial

- Voriconazole is a triazole antifungal and a synthetic derivative of fluconazole.
- It is used mainly in immunocompromised patients for the treatment of invasive aspergillosis, serious infections caused by *Scedosporium* spp., *Fusarium* spp., and invasive fluconazole-resistant *Candida* spp. (including *C. krusei*).

### 858 | Voriconazole

Parenteral therapy should only be used where the oral route is unavailable; voriconazole has an
oral bioavailability of 96%. The oral route is specifically preferred in ↓renal function because of
potential toxicity resulting from one of the excipients of the IV form.

### **Pre-treatment checks**

- Do not give in acute porphyria.
- Use with caution in patients with potentially pro-arrhythmic conditions (cardiomyopathy, jpulse, symptomatic arrhythmias, history of QT interval prolongation, or concomitant use with other drugs that prolong QT interval), and in those at risk of pancreatitis.
- · Check for specific drug interactions (many contraindications).

#### Biochemical and other tests (not all are necessary in an emergency situation)

 Bodyweight

 Electrolytes: serum K, Mg, Ca (disturbances
 LFTs

 should be corrected prior to initiation of
 Renal function: U, Cr, CrCl (or eGFR)

 therapy)
 therapy

### Dose

Loading dose: 6 mg/kg by IV infusion every 12 hours for 2 doses.

**Maintenance dose:** 4 mg/kg by IV infusion every 12 hours (reduced to 3 mg/kg every 12 hours if not tolerated). Voriconazole has a high oral bioavailability (96 %) so switch to oral administration as soon as possible.

**Dose in renal impairment**: dose as in normal renal function but if CrCl < 50 mL/minute there is a risk of accumulation of the IV vehicle (sulfobutylether beta cyclodextrin sodium [SBECD]). The oral form should be used unless it is judged that the benefit outweighs the risk; Cr should be closely monitored.

**Dose in hepatic impairment:** in patients with a Child–Pugh Class A or B use the standard loading dose but half the maintenance dose. It has not been studied in patients with a Child–Pugh Class C.

### Intravenous infusion

- 1. Reconstitute each vial with 19 mL WFI. Discard the vial if the vacuum of the vial does not pull the diluent into the vial.
- 2. Shake until dissolved to give a solution containing 10 mg/mL.
- 3. Visually inspect and only use if clear and particle-free.
- Withdraw the required dose and add to a suitable volume of compatible infusion fluid to give a solution containing 0.5–5 mg/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 6. Give by IV infusion at a maximum rate of 3 mg/kg/hour over 1-2 hours.

| Pharmacokinetics                          | Elimination half-life is 6 hours.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |
| Significant<br>interactions               | <ul> <li>Efavirenz may ↑voriconazole levels or effect (or ↑side-effects):<br/>Restrict doses of efavirenz to 300 mg/day and double the voriconazole dose. Monitor for any toxicity and/or lack of efficacy when given with efavirenz or nevirapine.</li> <li>The following may ↓voriconazole levels or effect:<br/>carbamazepine, phenobarbital, rifampicin, high-dose ritonavir and St John's wort (avoid). Low-dose ritonavir should be avoided also unless risk/benefit justifies the use of voriconazole. Phenytoin should be avoided if possible - if it cannot, monitor phenytoin levels and increase maintenance dose of voriconazole to 5 mg/kg every 12 hours. Rifabutin should be avoided if possible - if it cannot, ↑maintenance dose of voriconazole to 5 mg/kg every 12 hours. Rifabutin more closely.</li> <li>Voriconazole may ↑levels or effect of the following drugs (or ↑side-effects): Terfenadine, astemizole, cisapride, pimozide and quinidine ↑risk of QT interval prolongation (avoid). Causes very large increase in sirolimus levels and may increase levels of ergot alkaloids (avoid). Ciclosporin dose should be halved, tacrolimus dose decreased by a third and levels monitored with dose adjustment as necessary (process reversed on ceasing voriconazole). Monitor prothrombin time if given with warfarin or other oral anticcagulants. Monitor blood glucose closely if taking sulfonylureas - possible ↑levels causing hypoglycaemia. May ↑statin levels therefore ↓statin dose. Shortacting opioids, e.g. alfentanil, fentanyl, sufentanil and also methadone may require a dose reduction and closer monitoring of respiratory function. Halve the dose of omeprazole - levels of both drugs may be raised.</li> </ul> |  |
| Action in case of overdose                | There is no specific antidote: treatment should be symptomatic. Voriconazole and the IV vehicle (SBECD) may be haemodialysed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |  |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

### Bibliography

SPC VFEND 50 mg and 200 mg film-coated tablets, VFEND 200 mg powder for solution for infusion, VFEND 40 mg/ml powder for oral suspension (accessed 3 April 2009).

## Zidovudine (azidothymidine, AZT)

#### 10 mg/mL solution in 20-mL vials

- · Zidovudine is a nucleoside reverse transcriptase inhibitor (NRTI) with antiviral activity against HIV-1.
- It is used with other antiretrovirals in the management of HIV infection because viral resistance occurs rapidly if zidovudine is used alone.
- It may be used alone to prevent vertical transmission from mother to infant if combination antiretroviral therapy is not available.

### **Pre-treatment checks**

Do not use in acute porphyria or breast feeding.

### Biochemical and other tests

Fasting serum lipids and blood glucose.

FBC (do not give if neutrophil count <7500 cells/mm<sup>3</sup> (<0.75 × 10<sup>9</sup>/L) or haemoglobin <7.5 g/dL), vitamin B<sub>12</sub> level ( $\uparrow$ risk of neutropenia if low).

LFTs.

Renal function: U, Cr, CrCl (or eGFR).

### Dose

**Management of HIV infection in patients temporarily unable to take zidovudine by mouth:** 1–2 mg/kg every 4 hours (approximating to 1.5–3 mg/kg every 4 hours by mouth) usually for not more than 2 weeks and as part of a multidrug treatment regimen.

**Prevention of maternal-fetal transmission:** pregnant women (over 14 weeks of gestation) should be given 500 mg/day orally (100 mg five times per day) until the beginning of labour. During labour and delivery 2 mg/kg should be given by IV infusion over 60 minutes followed by 1 mg/kg/hour by continuous IV infusion until the umbilical cord is clamped.

- In case of planned caesarean, the infusion should be started 4 hours before the operation.
- In the event of a false labour, the infusion should be stopped and oral dosing restarted.
- NB: newborn infants should be given 2 mg/kg bodyweight orally every 6 hours starting within 12 hours of birth and continuing until they are 6 weeks old.
- Infants unable to receive oral therapy should be given 1.5 mg/kg by IV infusion over 30 minutes every 6 hours.

Dose in renal impairment: adjusted according to creatinine clearance:

- CrCl 10-50 mL/minute: 1-2 mg/kg every 8 hours.
- CrCl <10 mL/minute: 0.5–1 mg/kg every 8 hours.</li>

**Dose in hepatic impairment:** dose reduction may be necessary. If it is not possible to monitor plasma zidovudine levels, monitor for signs of intolerance e.g. anaemia, leucopenia, neutropenia and  $\downarrow$  dose and/or  $\uparrow$  interval between doses as appropriate.

### Intravenous infusion

- 1. Withdraw the required dose and add to a suitable volume of Gluc 5% to give a solution containing 2-4 mg/mL.
- The solution should be clear and nearly colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV Infusion over 60 minutes (see information above regarding the continuous infusion in prevention of maternal-fetal transmission). Discard the solution if it goes turbid during the infusion.

| Pharmacokinetics                             | Elimination half-life is 0.5-3 hours.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Significant<br>interactions                  | <ul> <li>The following may †zidovudine levels or effect (or †side-effects):<br/>fluconazole, ganciclovir (risk of profound myelosuppression, avoid<br/>combination if possible), probenecid, ribavirin (†risk of anaemia, avoid<br/>combination), valproate (†risk of haematological toxicity).</li> <li>The following may ‡zidovudine levels or effect:<br/>rifampicin (manufacturer advises avoid combination), tipranavir.</li> <li>Zidovudine may †levels or effect (or †side-effects) of phenytoin (monitor levels).</li> <li>Zidovudine may ↓levels or effect of the following drugs:<br/>phenytoin (monitor levels), stavudine (avoid combination).</li> </ul> |
| Action in case of<br>overdose                | No specific antidote, management should be supportive as appropriate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Counselling                                  | Patients should be advised to seek medical advice if they experience joint aches<br>and pain, joint stiffness or difficulty in movement - possible signs of osteonecrosis.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

### Bibliography

SPC Retrovir 10 mg/mL IV for infusion (accessed 3 April 2009).

## Zoledronic acid

### 0.05 mg/mL solution in 100-mL vial (Aclasta); 0.8 mg/mL solution in 5-mL vial (Zometa)

- Zoledronic acid is an aminobisphosphonate with properties similar to other bisphosphonates. It inhibits bone resorption, but appears to have less effect on bone mineralisation.
- Aclasta is a ready-to-use solution for infusion licensed for use in osteoporosis (postmenopausal women and men) and in Paget's disease.
- Zometa is a concentrate licensed for use in advanced malignancy associated with bone involvement and ↑Ca.
- Doses are expressed in terms of the anhydrous form: Zoledronic anhydrous  $1 \text{ mg} \equiv 1.066 \text{ mg}$  zoledronic acid monohydrate.

### **Pre-treatment checks**

- Do not give to patients already receiving other bisphosphonates.
- Osteonecrosis of the jaw can occur: consider dental examination and preventive dentistry prior to *planned* treatment in patients with risk factors (e.g. cancer, chemotherapy, radiotherapy, corticosteroids, poor oral hygiene). Avoid invasive dental procedures during treatment if possible.
- Give cautiously to patients who have had previous thyroid surgery (increased risk of  ${\downarrow}Ca$ ).
- Contraindicated in pregnancy and breast feeding. Women of child-bearing potential should take contraceptive precautions during *planned* treatment.
- For all indications other than ↑Ca prescribe oral calcium and vitamin D supplements in those at risk of deficiency (e.g. through malabsorption, lack of exposure to sunlight or inadequate dietary intake) to minimise ↓Ca.
- Hydrate the patient adequately before, during and after infusions (up to 4L may be given over 24 hours but overhydration should be avoided; risk of cardiac failure). Especially important in especially elderly patients and those receiving diuretic therapy.

### Biochemical and other tests

Electrolytes: serum Na, K, Ca,  $PO_4$ , Mg FBC Renal function: U, Cr, CrCl (or eGFR) – check before every dose<sup>1</sup>

### Dose

**Osteoporosis** (Aclasta): 5 mg by IV infusion once a year. Do not give in severe renal impairment (CrCl or eGFR <35 mL/minute).

**Paget's disease** (Aclasta): 5 mg by IV infusion as a single dose. Do not give in severe renal impairment (CrCl or eGFR <35 mL/minute). Specific information on re-treatment is not available.

**Tumour-induced hypercalcaemia**, i.e. corrected serum Ca  $\geq$ 3 mmol/L (Zometa): 4 mg by IV infusion as a single dose. Repeat if clinically necessary after a period of at least 7 days. Do not give in severe renal impairment (Cr  $\geq$ 400 micromol/mL).

**Prevention of skeletal-related events in patients with advanced malignancies involving bone** (Zometa): 4 mg given by IV infusion every 3–4 weeks. Reduce the dose in renal impairment (see Table Z1). Withhold if renal function deteriorates (see Monitoring).

| Baseline CrCl (mL/minute) | Zometa dose (mg) for prevention of skeletal-related events |  |
|---------------------------|------------------------------------------------------------|--|
| <30                       | Not recommended                                            |  |
| 30-39                     | 3 mg                                                       |  |
| 40-49                     | 3.3 mg                                                     |  |
| 50-60                     | 3.5 mg                                                     |  |
| >60                       | 4 mg                                                       |  |

### Table Z1 Dose adjustment in renal impairment

### Intermittent intravenous infusion (Aclasta)

### Preparation and administration

- 1. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration.
- 2. Give by IV infusion directly from the bottle via a vented infusion line, over at least 15 minutes.

### Intermittent intravenous infusion (Zometa)

The patient must be adequately hydrated using NaCl 0.9% before dosing for  $\uparrow$ Ca. Zoledronic acid is incompatible with Hartmann's and Ringer's (contain Ca).

- 1. Withdraw the required dose (see Table Z2) and add to 100 mL of NaCl 0.9% or Gluc 5%.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration.
- 3. Give by IV infusion over at least 15 minutes.

## **Zuclopenthixol acetate**

### 50 mg/mL oily solution in 1-mL and 2-mL ampoules

#### This preparation must not be confused with the depot preparation.

- · Zuclopenthixol acetate is a thioxanthene antipsychotic with a wide range of actions.
- It is used in the short-term management of acute psychoses including mania and exacerbation of chronic psychoses.
- The NICE clinical guideline on violence recommends that use of zuclopenthixol acetate may be considered in the following circumstances:
  - · Where the patient is expected to be disturbed/violent over an extended period of time.
  - Where the patient has a past history of a good response to zuclopenthixol acetate injection.
  - Where the patient has a past history of requiring repeated parenteral administration of antipsychotics or benzodiazepines.
  - Where an advance directive has been made.

### **Pre-treatment checks**

- Do not give to patients in comatose states, including alcohol, barbiturate or opiate poisoning.
- Do not give to patients who have never received antipsychotic medication or patients who are struggling.
- · Caution in epilepsy and hepatic, renal or cardiovascular disease.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Review the patient's physical health including LFTs current physical observations and recent ECG. Renal function: U, Cr, CrCl (or eGFR) Blood pressure

### Dose

**Short-term management of acute psychoses:** 50-150 mg (1-3 mL) repeated if necessary after 2–3 days. If required, an additional injection may be given 1–2 days after the first injection. The maximum cumulative dose is 400 mg per course of treatment. The duration of treatment should not exceed 2 weeks (maximum 4 injections).

**Dose in renal impairment:** the dose should be reduced by half. **Dose in hepatic impairment:** the dose should be reduced by half.

### Intramuscular injection

- 1. Withdraw the required dose.
- 2. Give by deep IM injection into the upper outer buttock or lateral thigh. Aspirate before injection to avoid inadvertent intravascular injection.

## **Zuclopenthixol decanoate**

200 and 500 mg/mL oily solution in 1-mL ampoules

This preparation is a depot preparation and must not be confused with the rapid-acting injection.

- Zuclopenthixol decanoate is a thioxanthene antipsychotic with a wide range of actions.
- As a long-acting depot injection it is used in the treatment of schizophrenia and other psychoses, particularly with aggression and agitation.

### **Pre-treatment checks**

- · Avoid in patients in comatose states, including alcohol, barbiturate, or opiate poisoning.
- · Concomitant treatment with other antipsychotics should be avoided.
- Caution in epilepsy, Parkinson's disease, liver disease, renal failure, cardiac disease, depression, myasthenia gravis, prostatic hypertrophy, narrow-angle glaucoma, hypothyroidism, hyperthyroidism, phaeochromocytoma, severe respiratory disease or if there are risk factors for stroke.

### Biochemical and other tests

| Blood pressure | LFTs                                  |
|----------------|---------------------------------------|
| Bodyweight     | Renal function: U, Cr, CrCl (or eGFR) |
| ECG            | TFTs                                  |
| FBC            |                                       |

### Dose

#### Treatment of schizophrenia and other psychoses:

- Test dose: 100 mg to assess tolerability. Reduce dose to 25 mg or 50 mg if the patient is elderly.
- Maintenance dose: To commence at least 1 week after test dose. Usual dose range is 200–500 mg every 1–4 weeks. The maximum dose is 600 mg weekly.

### Intramuscular injection

- 1. Withdraw the required dose.
- Give by deep IM injection into the upper outer buttock or lateral thigh. Volumes >2 mL should be distributed between two injection sites. Aspirate before injection to avoid inadvertent intravascular injection. Rotate injection sites for subsequent injections.

### 872 | Zuclopenthixol decanoate

# Appendix 1 The basics of injectable therapy

### The basics

The use of parenteral therapy is part of daily practice in hospitals and increasingly so in primary care. Using the parenteral route to administer medicines requires all practitioners to work in partnership to ensure the safe, effective and economic use of parenteral therapy.

Safe systems of practice must be put in place to ensure aseptic techniques are adhered to throughout all parenteral procedures and to minimise drug-related errors. All practitioners involved with any aspect of parenteral drug therapy must adhere to the recommendations of their own professional bodies, and must also work within their own organisation's procedures regarding medicines management and patient care.

This book may be used as a reference source by all practitioners: doctors, nurses, midwives, pharmacists, operating department practitioners (ODPs with NVQ Level 3 qualification) and other suitably qualified personnel who have been trained and assessed as competent to administer drugs by the parenteral route.

### **General information**

The monographs in this book detail appropriate methods of administration for medicines that can be given via the parenteral route. They must be used in conjunction with any polices and/or procedures recommended by the practitioner's own governing body, e.g. in the UK the most recent edition of The Royal Marsden Hospital Manual of Clinical Nursing Procedures<sup>1</sup> or a local Medical Devices Policy. Cancer chemotherapy agents are not included in this guide as they should only be administered by formally trained and qualified nurses and doctors. Practitioners requiring additional information relating to the handling and administration of these medicines should contact their own Pharmacy department.

There may be times when a patient's clinical status justifies a change from the instructions in the monograph. In this situation the nurse or doctor should contact their Pharmacy Medicines Information department or call their resident or on-call pharmacist for further instructions on how to administer the relevant drug.

### **Sodium content**

The sodium content of each medicine is included in this guide. Some medicines, e.g. many antibiotics, are formulated with a considerable sodium content; for example, metronidazole contains 13.15 mmol/ 500-mg bag. This may be clinically significant and may need to taken into account when therapeutic choices are made. In the monographs the sodium content is listed if a dose contains  $\geq 1$  mmol sodium.

### рΗ

An indication of the acidity or alkalinity of injection solutions has been included in the monographs (as measured by their pH) to help practitioners predict possible Y-site incompatibilities of medicines when no compatibility information exists.

Injections with greatly differing pH values should not be administered concurrently down the same line as this may result in either precipitation or inactivation of the medicines<sup>2</sup>; for example, the pH of phenytoin injection is 12 and the pH of haloperidol injection is 3, making them incompatible; if mixed they would combine chemically to form a precipitate.

The pH can also give the practitioner an indication of the irritancy of the drug. Medicines that are either highly acidic or alkaline may be harmful if extravasation into the surrounding tissue occurs, causing tissue damage.

Injections in oily or other unusual vehicles do not have a pH value. This is because pH is a measure of the acidity or alkalinity of an aqueous solution and by its very nature an oily injection is not an aqueous solution.

### **Light-sensitive infusions**

Some drugs undergo photolysis and photodegradation if exposed to natural daylight (ultraviolet radiation) and fluorescent light during administration. This can result in loss of therapeutic effect and the production of toxic products.

To reduce these reactions, the products must be protected from light not only during storage but also once diluted and ready for use. The infusion bag, the syringe and sometimes the giving set need to be protected from light by covering with an opaque material or aluminium foil.

Periodic visual inspection of the diluted solution for the occurrence of discoloration and/or precipitation is recommended during its infusion.

Drugs that must be protected from light have this detailed in their individual monograph.

### **Displacement value**

Injection products formulated as dry powders or lyophilised cakes must be reconstituted with a suitable diluent before administration. Sometimes the final volume of the injection is greater than the volume of liquid added to the powder. This volume difference is called the displacement value; for example:

- The displacement value of amoxicillin injection 250 mg is 0.2 mL.
- If 4.8 mL of diluent is added to a 250-mg vial, the resulting volume is 5 mL, i.e. 250 mg in 5 mL.
- If 5 mL of diluent is added, the resulting volume is 5.2 mL, i.e. 250 mg in 5.2 mL or 240.38 mg in 5 mL.

Drugs that have a significant displacement have this detailed in their individual monograph and this must be taken into account when reconstituting the drug if only part of the vial is to be used. If the total content of a vial is to be given, the displacement value need not be taken into account when reconstituting the drug because the entire contents of the vial are withdrawn for administration.

### Visual inspection of prepared product

All products prepared for intravenous use make reference to this requirement as part of the preparation procedure. Products to be given by other routes should also be inspected prior to administration. This is because it is possible for particulate matter to be present in the final product, often from the rubber bung of the vial shedding material when punctured by a needle.

The following technique describes a method for visually checking the product. Hold the syringe or infusion container up to a light source and, while looking straight through the solution, invert the product. Usually all that is seen are air bubbles swirling and moving in a general upwards direction, but observe for a few seconds for anything (particles) moving downwards and any untoward colour changes as described in the specific monograph.

### Blood and blood products and parenteral nutrition (PN)

In the UK the Department of Health states that the co-administration of blood or concentrated red blood cells with any other medicine or vehicle is hazardous. The same caution should also be

applied to bags of parenteral nutrition. The reason for such caution is that large molecules may form in the bag that could cause anaphylaxis or seed an embolism. As the contents of these bags are opaque, visual clues to such reactions cannot be seen.

If additional fluid or electrolytes are needed then these must be run separately via a different line if possible. If the same line must be used, all practitioners **must** check with their pharmacist about compatibilities as certain electrolytes/hyperosmolar fluids may cause precipitation of the PN/blood in the line.

### Flushing intravenous lines and cannulas<sup>1,2</sup>

Flushing between the administration of different medicines must always be carried out to avoid any problems with incompatibilities. Flushing also ensures the total drug dose is presented for systemic effect and prolongs the viability of the cannula or line.

If two drugs being administered one after the other are known to be compatible, then flushing the line or cannula need only be done before and after administration of the medicines. Commonly 5–10 mL of NaCl 0.9% or Gluc 5% is used to flush the dead space of a cannula, whereas 20 mL is usually needed for an administration set. The practitioner must check each monograph before deciding which flush to use, to ensure that both drugs are compatible with the chosen flush.

Frequent flushing of unused lines is also necessary in order to maintain patency of the line or cannula. The National Patient Safety Agency has recently recommended the exclusive use of NaCl 0.9% injection as a flush for maintaining peripheral intravenous cannulas.<sup>3</sup>

Occasionally NaCl with heparin is required to ensure that certain lines are kept patent, but such use should be kept to a minimum. If the use of a heparin flush is appropriate then it must be administered against a valid prescription. Practitioners should check their individual organisation's policies in order to determine when the use of a heparin flush is appropriate.

### **Central versus peripheral access**

Before a medicine can be administered intravenously, a suitable intravenous catheter must be inserted into the patient. These can either be central intravenous catheters, peripheral intravenous catheters or peripherally inserted central intravenous catheters (PICC lines). Choice of line is often dictated by the clinical condition of the patient; for example, a critically ill patient is more likely to require central access than a patient who only requires a few days' intravenous therapy.

Unlike peripheral catheters, central lines are generally thought to last longer, are more consistently accessible regardless of the patient's condition and can accept more irritant solutions, e.g. hyperosmolar or vasoconstricting drugs. Central catheters also carry the advantage of allowing a rapid rate of infusion of a drug and can be used to monitor central venous pressures as well as aid the passing of pulmonary artery catheters. However, insertion of central intravenous catheters requires greater skill and the risks associated with them are greater.<sup>4</sup>

A peripheral catheter is appropriate if the patient is not receiving irritant solutions intravenously, if intravenous therapy is likely to be short term and if suitable vein(s) are available for cannulation.

Central and peripheral catheters are often referred to in the vernacular as central lines and peripheral lines. For more information see Appendix 7 Intravascular devices.

### Glucose or dextrose: which term to use?

The term glucose (abbreviated to Gluc in this book) is used throughout the monographs to define the injection and infusion fluid of that substance. The term dextrose is used by some authorities and on occasion this been known to lead to confusion.

Glucose is a three-dimensional molecule that exists in two symmetrical forms (mirror images of each other) and the *dextro-* and *laevo-* prefixes are used to categorise the forms that can rotate plane-polarised light clockwise (to the right) or anticlockwise (to the left) respectively.

The word dextrose is a contraction of *dextrorotatory glucose* or *d*-glucose, which is the biologically active form of glucose, as opposed to *laevorotatory glucose* or *l*-glucose (which is not biologically active).

The colloquial naming system can lead to further confusion when applied to the less frequently used injection fructose, which has been referred to as laevulose as it is the laevorotatory form of fructose. It is however structurally different from glucose and is not the laevorotatory form of glucose.

### Osmolarity

Osmolarity is stated in some monographs only for those drugs that have a high osmolarity. The significance of this is that at a solution of high osmolarity can cause serious harm to small blood vessels and these drugs would not normally be appropriate for peripheral administration. In general solutions of high osmolarity should be given centrally.

It is worth explaining what the term means and how it differs from the similar term osmolality. *Osmolarity* is a measure of solute concentration in terms of osmoles per litre of solution (Osmol/L), whereas *osmolality* is a measure of the number of osmoles of solute per kg of solvent (Osmol/kg). Calculated figures for both are very similar and the terms are used interchangeably in practice with little consequence.

An osmole (Osm or Osmol) is a unit of measure that describes the number of moles of a chemical compound that contribute to a solution's osmotic pressure, that is, the pressure that must be applied to a solution to prevent the inward flow of water across a semi-permeable membrane.

# Appendix 2

# Good management principles

It is unacceptable to prepare medicines for administration by others. The practitioner administering the drug must be involved in the preparation and checking process. The following are exemptions from this principle:

- · Injections and infusions prepared by the Pharmacy department.
- Drugs prepared for/by anaesthetists (however, this practice is only acceptable when carried out on the instructions and in the presence of a doctor who witnesses and checks the preparation).

Parenteral drugs must not be prepared in advance of their immediate use (except when prepared by the Pharmacy).

Parenteral medicines should be prepared in a designated clean area.

Parenteral medicines do not routinely need to be double-checked by another practitioner; however, each practitioner should check their own organisation's policy on this matter before administering a medicine. It is good practice to request a double check on administration if:

- The infusion involves the addition or mixing of drugs, e.g. the reconstitution of a powder to make a solution for injection does not need to be double checked.
- A Controlled Drug is involved.
- A calculation is involved.

Local circumstances may make involvement of a second practitioner desirable in order to minimise the potential for error, e.g. on a neonatal unit.

Each practitioner is responsible for maintaining his or her own knowledge on all drugs. Information on such products can be found in the monographs of this book, in the package insert and/or via the Pharmacy department.

In the UK practitioners requiring further information on the advantages and disadvantages of using any parenteral route and the principles of preparation and administration of intravenous drugs should see the Drug Administration Section of the most recent edition of The Royal Marsden Hospital Manual of Clinical Nursing Procedures or similar texts.

### **Minimising risk of infections**

Practitioners should ensure that they:

- Always use an aseptic non-touch technique (ANTT) when administering parenteral medicines.
- · Minimise unnecessary disturbance or movement of the line/cannula.
- Cover the intravenous site with a transparent occlusive dressing so that the point of insertion into the vein is clearly visible.
- · Inspect the site daily for signs of redness, swelling, inflammation; etc.
- Re-site all lines/cannulas that are thought to be infected and take cultures (see individual organisation's policies on taking blood cultures).
- Avoid using 3-way taps, ports, etc. wherever possible as these do not provide an effective barrier against entry of microorganisms.
- Change the line/cannula and the giving set at the intervals recommended by their own organisation's policies.

Practitioners should contact their Infection Control department for more guidance on aseptic non-touch technique (ANTT) in their organisation. Further information is also available at http://www.antt.co.uk/.

### Accountability

Parenteral therapy is a common and important part of the care received by many patients. It also carries the risk of potentially dangerous complications. In order to protect patients and provide staff with the means to deliver safe and effective treatment, the practitioner should always follow guidance issued by their own organisation.

In the UK the NHS requires that all practitioners involved in the administration of parenteral medicines should achieve an appropriate level of competence according to the procedure being undertaken, the drug involved and the device being used.

As nurses/midwives administer the majority of parenteral therapy, NHS organisations require that they provide evidence of competence through successfully completing an approved Parenteral Therapy course/programme before undertaking assessment in the clinical area.

In order to provide comprehensive patient care all nurses/midwives are expected to achieve competency at the earliest opportunity following appointment and may be called on to demonstrate their competency at any time. Although nurses/midwives can decline to perform duties in which they do not feel competent, they are obliged to adapt to new methods and techniques of administering medications and must work at a level commensurate with the grading of their role. Parenteral therapy, in particular, is an area that is continually evolving and can be considered to be an integral part of the nurse's or midwife's role and thus every effort must be made to achieve competence in this area of practice.

All practitioners have a duty of care to their patients, who are entitled to receive safe and competent care. If a practitioner is asked to perform a duty which is outside their area of expertise they must obtain help and supervision from a competent practitioner until they and the Trust consider they have acquired the requisite knowledge and skills.

# Appendix 3 Usual responsibilities of individual practitioners

### The prescriber<sup>1</sup>

- The prescribing of parenteral medicines or fluids is the responsibility of a doctor, or an independent or supplementary prescriber. The prescription must clearly state:
  - Approved name
  - Dose and frequency of the drug
  - Method of administration and by which route central or peripheral, intramuscular, subcutaneous, etc.
  - · Type and volume of fluid for dilution or infusion
  - Final concentration
  - Calculated infusion rate.
- The prescriber must restrict the use of the parenteral route to situations where there is no clinically effective alternative method for administration of the medicine.
- The prescriber must review the patient on a daily basis to keep parenteral therapy to the minimum effective duration.
- The prescriber must ensure that the vascular access device to be used, e.g. Venflon, is appropriate for the needs of the individual patient and the drug to be administered.

### The pharmacist<sup>1,2</sup>

The Pharmacist (or Pharmacy service) has the role of:

- Monitoring the safety of the drug use process and alerting prescribers and other health care professionals to potential problems.
- · Checking the selection of drugs and regimens to ensure appropriate treatment.
- Endorsing the prescription chart (or other prescribing system) with relevant and necessary information on dilution and rates of administration, etc. in accordance with pharmacy procedures.
- Providing information to specific enquiries raised by health care professionals on all aspects of intravenous therapy, e.g. diluents, drug stability, adverse effects and compatibility, etc.
- · Checking the lines and/or administration devices, e.g. syringe and infusion bag, are labelled correctly.

### The practitioner administering the parenteral drug<sup>3</sup>

For in-patients the practitioner preparing and administering the drug (not the second checker) must:

• Appropriately identify the patient by checking their name and hospital identification number on an identity band (or an alternative as defined within the organisation's patient identification policy) before administering the drug.
## 882 | Appendix 3 Usual responsibilities of individual practitioners

In all cases the practitioner preparing and administering the drug must:

- Check the patient is not allergic and/or sensitive either to the drug or any of the constituents of the injection by checking the allergy status of the patient.
- Be in possession of sufficient information to ensure competence in the safe administration of the drug (including information on unlicensed medicines, clinical trial medicines or licensed medicines that are not licensed for the particular indication, dose, age group or route of administration).
- Seek advice if unsure of any aspect of the administration of a drug by the intravenous route.
- Ensure that any vascular access device used is appropriate for the needs of the individual patient and the drug to be administered.
- Check when the cannula in use was sited before administering any drugs through it, and ensure all
  peripheral cannulas are re-sited every 72 hours or earlier if any signs of phlebitis are evident.
- Ensure that an assessment of the venous access site is undertaken prior to, during and after drug
  administration, and that this assessment is documented in accordance with their own
  organisation's policies.
- Ensure that the cannula or line is flushed using the appropriate flush before and after the administration of all parenteral drugs as indicated under Flushing intravenous lines and cannulas in Appendix 1.
- Be familiar with and competent to use any equipment required as part of the drug administration process.
- Ensure the lines and/or administration device are correctly labelled.
- Monitor all infusions throughout administration to ensure that the infusion is being administered
  at the correct rate, that the infusion pump or device is working as intended, and that the patient is
  responding to the infusion therapy as intended.
- Be aware of, and be able to monitor for both immediate and delayed side-effects including hypersensitivity reactions or signs of extravasation and be able to respond appropriately if they occur.
- Ensure that accurate documentation of drug administration is maintained, including fluid balance for intravenous infusions.

# Appendix 4 Advantages and disadvantages of parenteral therapy

There are many advantages to using the parenteral route to administer medicines, but because of the potential risks to the patient the practitioner should always carefully consider all advantages and disadvantages before using the parenteral route.

Advantages include:

- Rapid effect, e.g. useful in an emergency (myocardial infarction, anaphylaxis, status epilepticus)
- · Usefulness for drugs that are not absorbed orally, e.g. insulin, heparin, some antibiotics
- · Constant therapeutic effect, e.g. inotropes, antipsychotics
- · The possibility of precise dosing, e.g. for anaesthesia, analgesia
- · Controllable rate of administration, e.g. morphine
- Co-operation of the patient is not needed, e.g. if the patient is unconscious, uncooperative or uncontrollable
- Usefulness if the patient is 'nil by mouth', not absorbing or unable to tolerate oral medicines (however, the topical and rectal routes may also be appropriate).

Disadvantages include:

- · Risk of infection
- · Dangerous and/or fatal if given incorrectly, e.g. potassium
- The dose is not retrievable
- Specialised technique is required to administer medicines
- · Training is required before the practitioner can administer medicines
- · Can be painful for the patient, or at the very least inconvenient
- Difficulty in self administration, e.g. for home intravenous antibiotics, which may lead to increased length of hospital stay
- High cost
- · Complications, e.g. extravasation, side-effects usually more immediate and severe
- · Compatibility and stability issues.

# Appendix 5 Injection techniques and routes

# Intermittent intravenous infusions

This is the technique used to administer an injectable drug in an intravenous infusion over a period of time ranging from 20 minutes to several hours. Repeated doses (e.g. benzylpenicillin) or single doses (e.g. furosemide) are given in this way.

The infusion may be connected to the primary intravenous giving set or to a secondary administration set via a Y-connector. Administration can also be via an in-line burette, which would normally constitute a section of the primary giving set.

The volume of intravenous fluid used to dilute the drug ranges from 50 mL (the smallest intravenous fluid bag) up to 500 mL. In clinical practice most drugs are given in 100 mL and are set to infuse over 20–30 minutes.

Advantages include:

- · A volumetric pump can be used to deliver the dose in a controlled way.
- · Fewer manipulations are required in preparation compared to use of a syringe driver.
- It is cheaper than using a syringe driver.

Disadvantages include:

- Aseptic technique is required for preparation unless prepared by a central intravenous additive service (CIVAS).
- Bags usually have limited stability once prepared, possibly resulting in waste unless carefully managed by CIVAS.
- · Patient mobility is restricted (at least during the administration).
- There is potential for extravasation at infusion site.
- Administration of intravenous fluid is required to maintain cannula patency.
- More invasive and expensive than enteral administration.
- · Multiple doses may result in fluid overload.

The usual diluent solutions are NaCl 0.9% and Gluc 5%, which are available in a variety of volumes. These concentrations are used because they are isotonic with blood and thus do not cause haemolysis of blood cells.

The drug to be given may be compatible with one or both of these, although solubility and stability times may differ. Infusion bags may contain about a 5% overage so the practitioner must take this into account if only using part of the bag.

Mixing drugs in infusion bags is not advised without compatibility data, which can be found in reference sources such as the latest edition of Trissel's *Handbook on Injectable Drugs*<sup>1</sup> or via a website such as MedicinesComplete (www.medicinescomplete.com).

## **Direct intravenous injections**

Some drug products may be administered directly into the venous circulation in a relatively small volume of fluid over less than 5 minutes. This technique is sometimes referred to as an 'IV push' or 'IV bolus'. The injection may be given:

- · Via an injection port in an infusion line
- Via an indwelling cannula, e.g. Venflon
- From a syringe and needle directly into a vein.

A direct intravenous injection (as opposed to an intravenous infusion) is used when:

- · Administration is urgent (e.g. tenecteplase).
- A high concentration of the drug is required (e.g. adenosine).
- Time is limited (in the anaesthetic room prior to a surgical operation).
- The patient is fluid-restricted.
- · Patient or carer convenience dictates (e.g. domiciliary antibiotics).
- It is recommended by the manufacturer.

Unless specifically directed otherwise by the manufacturer, a direct intravenous injection is given over 2–3 minutes, observing the patient and the injection site for signs of adverse reaction.

The volume of injection is usually 5 mL or less, although larger volumes may be necessary if the drug has low solubility, is likely to be an irritant to the vein or requires relatively slow administration.

Bolus injections into indwelling cannulas should always be preceded and followed by at least 2–5 mL of a flushing solution.

Some drugs are too irritant or toxic to be administered as a concentrated injection; for example, erythromycin is too painful and irritant to the vein, while potassium chloride 15% injection is too toxic to the myocardium in high concentration (and also extremely irritant).

### Intramuscular injections

Intramuscular injections are administered into the muscle beneath the subcutaneous tissue, and are generally absorbed faster than subcutaneous injections. They are most commonly given into the thigh or the gluteal muscle, and occasionally into the deltoid muscle (which attaches the upper arm to the shoulder).

The volume given at any one site is usually limited to 5 mL for the thigh (or 4 mL if it is a depot injection because depots can be more irritant), and 2 mL for the deltoid muscle.<sup>2</sup> Larger volumes are not effectively absorbed and if given may lead to abscess formation. If more than 5 mL has to be given, then more than one injection site should be used. If a series of injections are to be administered, injection sites should be used in rotation and a record of these kept.

The two most common ways of giving an intramuscular injection are by:

- Direct injection straight into the muscle, with the needle held at a 90° angle to the skin. Upon removal, pressure should be applied to the injection site to prevent leakage.<sup>3</sup>
- Z-track technique wherein the skin above the muscle is displaced sideways, so that when the
  needle is withdrawn the skin can be simultaneously released. This has the effect of sealing the
  injection under the skin and preventing leakage into the subcutaneous tissue.<sup>2</sup> The Z-track
  technique is notably recommended for iron injections to minimise subcutaneous irritation
  and staining.

#### Relative bioavailability

There may be bioavailability differences between intramuscular and intravenous administration of certain drugs, and the intramuscular route is usually associated with a delayed onset of action. It is therefore incorrect to assume that a drug dose is interchangeable between the intravenous and intramuscular routes.

It is also considered to be an unsafe prescribing practice to specify alternative routes for the same prescription entry on a prescription chart.

## Subcutaneous injections<sup>4</sup>

Subcutaneous injections are given by injecting a fluid or a solid pellet into the subcutis (the fatty layer of tissue just under the skin). Subcutaneous injections of fluid are used to administer vaccines and medications, e.g. insulin. A pellet may be injected to deliver long-lasting doses of medication, e.g. goserelin. The technique provides slow and constant absorption of a drug or fluid.

Appropriate sites for a subcutaneous injection include:

- · The outer aspect of the upper arm
- · The anterior aspect of the upper arm
- · The abdomen below the costal margins to the iliac crests
- · The anterior aspect of the thigh
- · The ventrodorsal gluteal area
- The scapular area.

The site must not be bruised, tender, hard, swollen, inflamed or scarred as this may hinder absorption and cause discomfort and injury to the patient.

Irritant medications should not be administered subcutaneously as they may cause tissue necrosis or a sterile abscess.

### Administering a subcutaneous injection

Generally 25- to 27-gauge needles are used of varying lengths depending on the drug to be administered. Pinch up a skin fold between the thumb and forefinger and hold throughout the injection.

The angle of insertion of the needle depends on the length of the needle used and on the size of tissue fold pinched at the chosen site; for example, if there is a 2.5 cm tissue fold or if a longer needle is used, insert at a 45-degree angle; if there is a 5 cm tissue fold or a shorter needle is used, insert at a 90-degree angle.

Without aspirating, the medication should be injected with a slow, steady pressure. Aspiration after insertion of the needle is not recommended as this may cause tissue damage, hematoma formation and bruising. The likelihood of injecting into a blood vessel is small.

The site should not be massaged after administration as this can damage the underlying tissue and cause the medication to be absorbed faster than intended.

### Intra-articular injections

Intra-articular injections are made into the synovial space of a joint. They are typically given to relieve pain or inflammation and restore function to a joint or joints as in rheumatoid arthritis.

Steroid injections are used, e.g. triamcinolone, methylprednisolone (with or without lidocaine), hydrocortisone or dexamethasone. The size of the dose given depends on the size of the joint to be injected.

Injections should not be carried out if there is any suspicion of infection in the joint or in the surrounding tissue, i.e. if there are open sores or ulcers on the skin.

Once the needle is inserted, a small amount of synovial fluid should be withdrawn (aspirated) into a syringe to confirm correct positioning. A separate syringe is then used to give the medication. The joint is gently massaged and moved to aid mixing of the medication and the synovial fluid, and to reduce the risk of a permanent depigmented 'steroid scar' developing.

In practice, if multiple joints are to be injected, it is not normal to inject more than five joints on the same day.

Other types of material used intra-articularly are sodium hyaluronate and Hylan G-F 20. These are used for the sustained relief of pain in osteoarthritis of the knee, and Hylan G-F 20 is also used for temporary replacement and supplementation of synovial fluid.

### Intraosseous injection<sup>5</sup>

In children under the age of 6 years, and especially under 1 year, the intraosseous route of administration is used when venous access is difficult, e.g. in a hypovolaemic child.

A specially designed needle is placed into the tibia through which fluids and drugs may be administered into the bone marrow. Any drug or fluid that can be administered intravenously may be given in this way but it must be administered under pressure.

## Other routes of injection

### Intrathecal

Intrathecal injection is an injection into the spinal canal (the intrathecal space surrounding the spinal cord). The blood-brain barrier acts as a barrier to the brain and some drugs are unable to cross it. By administering these drugs intrathecally they are administered straight into the brain and so bypass the blood-brain barrier altogether. This route allows high concentrations of drugs – cancer chemotherapy agents, antibiotics etc. – to be administered directly to their site of action in the brain and spinal cord. Drugs given intrathecally have to be made up in a CIVAS unit because they cannot contain any preservative or other potentially harmful inactive ingredients that are sometimes found in standard injectable drug preparations.

#### Epidural

An epidural is a form of regional anaesthesia involving injection of drugs through a catheter placed into the epidural space. The injection can cause both a loss of sensation and a loss of pain by blocking the transmission of signals through nerves in or near the spinal cord.

#### Intracardiac

Intracardiac injection is administered directly into the heart muscles or ventricles. This route may sometimes be used in a cardiovascular emergency.

### Intradermal

Intradermal injection is injection into the skin itself. This route is used for skin testing, e.g. allergens, tuberculin PPD for Mantoux tests and for some vaccines, e.g. BCG vaccine.

### Intraperitoneal

The intraperitoneal involves an infusion or injection into the peritoneal cavity.

### Intravitreal

This is an injection delivered directly into the eye, usually into the vitreous cavity. 'Intravitreal' literally means 'inside an eye'.

# Appendix 6 Extravasation

Extravasation is a complication of intravenous injection therapy. It manifests as tissue damage or irritation caused by inadvertent placement or leakage of a drug into the area around the injected vein.

Although most awareness of this problem relates to cytotoxic agents, it is important to note that it is a possibility for all drugs that can be given intravenously, e.g. antibiotics, drugs that are highly alkaline or acidic and glucose infusions.

Drugs can be classified as vesicant (literally meaning 'to cause blisters or blistering') which cause direct damage to the vasculature, or as non-vesicant, which are further classified as irritant or non-irritant. Vesicants can cause extensive necrosis. Irritants can cause pain at the injection site and along the vein, with or without inflammation.

The following general rules can help to minimise the risk of extravasation:

- · Administration should be restricted to individuals familiar with the drugs and techniques used.
- The drug should be reconstituted appropriately to avoid administration of damaging concentrations.
- The drug should be given by via the injection port of free-flowing drip.
- The site of administration should be selected to take into account visibility, vessel size, amount of
  movement and potential damage if extravasation occurs. The optimum location is usually the
  forearm, which has superficial veins with sufficient soft tissue to protect tendons and nerves.
- The limb should be elevated with maintenance of gentle pressure after the needle is withdrawn.

### Suggested administration procedure

- 1. Insert a 23-gauge butterfly needle into the vein; a Teflon catheter may be preferred for longerduration infusions.
- 2. Lightly tape the tubing in place; do not obscure the injection site by taping.
- 3. Connect a NaCl 0.9% infusion to the butterfly needle. Allow about 5 mL of the solution to run through, then withdraw a small amount of blood to test the vein integrity and flow. Observe for extravasation and if this is obvious select another site. Avoid a distal point on the same vein.
- 4. Repeatedly ask the patient if he/she feels any pain or burning, and visually check the site. For an infusion, check every 2–3 minutes that it is still running.
- Following the drug injection, reconnect the NaCl 0.9% infusion and run through at least 5 mL of the solution to flush the drug from the entire tubing and needle.

If more than one drug is prescribed, inject the vesicant agent first; if all drugs are vesicant, inject the one with the smallest volume first.

Separate each drug administration by a 3–5 mL NaCl 0.9% flush. The rationale behind the administration of the vesicant first is that the integrity of venous access decreases with time and therefore if vesicants are administered first, all agents can be administered.

# **Extravasation treatment**

If extravasation occurs, treatment is critical and specific antidotes may be required for some drugs. The general recommendations in the management of extravasation are:

- 1. Stop the infusion/injection immediately.
- Remove the infusion bag/syringe. Do not flush. Do not remove the needle. Mark the area with an indelible pen.
- 3. Attempt to aspirate as much of the drug as possible with a clean syringe.
- 4. Apply a cool compress, which should be maintained for 1 hour.
- 5. Check for specific antidotes if applicable.
- 6. Apply hydrocortisone 1% (cream is easier to apply than ointment) topically to the affected area.

In the UK all extravasation injuries should be recorded and details sent to the green card reporting scheme run by the National Extravasation Service (www.extravasation.org.uk/home.html).

# Appendix 7 Intravascular devices

Central lines are long, hollow tubes made from silicone rubber, also referred to as skin-tunnelled central venous catheters. Examples of some of the branded devices that are used include Hickman and Groshong.

The central line is inserted (tunnelled) under the skin of the chest into a vein. The tip of the tube rests in the superior vena cava just above the heart (Fig. A7.1). They are frequently used in the administration of drugs and parenteral nutrition when the peripheral or oral routes are inappropriate. They are also used when the intravenous drug/infusion characteristics such as concentration, pH or osmolarity require their use.

All central venous catheters must be flushed before and after each drug administration and at least on a weekly basis with NaCl 0.9%. In some instances, a heparin solution, e.g. Hepsal is left in the device line (this is sometimes referred to as a 'lock technique'). The volume required depends on the line used. The tunnel insertion site on the skin surface of the chest should be covered with a dressing and changed twice a day.

A peripherally inserted central catheter (PICC) line is a long, thin, flexible tube that is inserted into one of the large veins of the arm near the bend of the elbow. It is then fed through the vein until the tip sits in a large vein just above the heart in a position similar to the central line (Fig. A7.2).

# Disadvantages

A number of problems can occur with both of these types of line, infection and clots being the most common.

Infections are treated empirically with systemic antibiotics and sometimes using an antibiotic lock technique whereby the antibiotic, usually teicoplanin (although gentamicin has been used) is injected into the catheter and left in place. This can be useful when trying to preserve the line. Alternatively, the line may be removed and replaced after resolution of any central infection.

Urokinase (licensed) or streptokinase (unlicensed) may be used to dissolve clots. See the relevant drug monographs for details.

# Appendix 8 Infusion devices

# General principles<sup>1</sup>

In the UK all pumps have been categorised as having either a high-, medium- or low-risk specification.

High-risk specification pumps infuse at higher accuracy rates, provide more consistent short- and long-term flow, incorporate comprehensive alarm features and deliver very low bolus doses on occlusion compared with medium- and low-risk pumps.

Practitioners should check with their Medical Devices department if they are unsure of the risk category of the pumps routinely used on their wards. It is the responsibility of the person administering the infusion to familiarise themselves with the type of infusion pump to be used and how to operate it safely.

## Using infusion pumps

An infusion pump must always be used in the following circumstances:

- To administer all infusions to patients under 16 years old.
- To administer parenteral nutrition.
- To administer certain other drugs (specified in the monographs of this book).

Before using an infusion pump always check the following:

- · All previously used pump settings have been cancelled.
- The pump is clean if not, ensure it is cleaned according to the manufacturer's instructions.
- The pump case and cable are intact if not, return it to the Medical Devices department.
- If the pump displays a 'service due' message return it to the Medical Devices department for an annual service.

An infusion pump should preferably be positioned at the same height as the infusion cannula insertion site. If positioned higher than 80 cm above the cannula insertion site the incidence of free flow and siphonage is increased, which may cause the pump to over-infuse.

Infusion pumps must be regularly checked throughout the administration of the infusion and the volume infused should be added to the patient's fluid balance chart.

All alterations to the settings of an infusion pump must be made by healthcare professionals who have been assessed as competent in using the device.

Infusion pumps must be cleaned by the practitioner disconnecting and removing the empty or unwanted infusion container after each patient.

All infusion pumps incorporate a backup battery. Infusion pumps should be kept plugged in to the mains when in use to ensure the backup battery is charged.

If an infusion pump is involved in an adverse incident the nurse in charge and the Medical Devices department must be informed immediately. The following actions must be taken:

- Close the roller clamp on the administration set.
- · Assess the patient and summon assistance if needed.
- Disconnect the administration set from the patient but do not remove the administration set/ syringe from the pump.
- Record any alarms on the pump, contents of the infusion container and rate of administration of the infusion.
- · Do not touch any of the keys on the pump except to switch it 'OFF'.
- Remove the pump from service and label it as defective.
- Complete an untoward incident form.

# Appendix 9 Syringe drivers

Syringe drivers are portable, battery-operated pumps delivering drugs at a predetermined rate by continuous subcutaneous infusion. The most common clinical use for the syringe driver is in palliative care when the oral route may not be available and other routes, e.g. rectal or sublingual, are not appropriate. Typical indications for their use are:<sup>1</sup>

- Dysphagia
- Unconsciousness
- Intractable nausea and vomiting
- Intestinal obstruction
- Malabsorption
- · Intolerability of the oral route.

Common infusion sites used are the upper chest wall, the upper arm or thigh, the abdomen and occasionally the back. Excessively hairy areas should be shaved before use.

Sites to be avoided include oedematous areas (due to poor absorption), adjacency of bony prominences or joints, inflamed or infected sites, the upper abdomen if there is an enlarged liver, the upper chest wall if the patient is very cachexic, and previously irradiated skin (within the last 8 weeks).

There are two types of driver commonly in use. One delivers medication by the hour and the other delivers medication by the day (or 24-hour period).<sup>2</sup> Many hospitals have adopted the policy of using only one type of driver to avoid the confusion associated with two products which are calibrated differently. Practitioners should check with their Medical Devices department which type is used in their organisation.

Often several medicines are mixed together and administered via a syringe driver. Standard reference sources should be consulted to check for compatibility, e.g. *The Syringe Driver*<sup>2</sup> or the *Palliative Care Formulary*<sup>3</sup>. The *British National Formulary* also carries some limited information about compatibilities in the section 'Prescribing in palliative care'.

If it is not possible for a practitioner to verify whether a particular combination of drugs is compatible, options include:

- · For a given indication, seeking alternate drugs for which compatibility has been validated
- · Using a second driver at a different site
- · Administering some drugs as subcutaneous injections, e.g. dexamethasone.

# Preparation of the syringe driver

- 1. Check that the driver is in full working order, and does not require a new battery.
- Calculate the volume of drugs to be given (before dilution) and pick an appropriate size of syringe to hold the final volume.
- 3. Draw up the required drugs and diluent (usually WFI or NaCl 0.9%) into the syringe. Consideration should be given to the order in which the drugs are introduced into the

syringe because of possible incompatibilities during the preparation process.<sup>2,3</sup> This is particularly critical if dexamethasone is to be mixed with other drugs; in this case, as much diluent as possible should be added to the syringe before the addition of dexamethasone.<sup>3</sup>

- 4. If the giving line requires priming with fluid, draw up an extra 1 mL of diluent.
- 5. The syringe should be labelled with the patient's name, the time and date of preparation and the drugs and doses contained. The label should not totally obscure the fluid in the barrel as this requires subsequent measurement.
- 6. The infusion set can then be primed if necessary with the infusion fluid to expel all the air from the tubing. The length of fluid in the syringe is then measured against the scale on the driver. This length is dialled into the driver to set the rate of movement of the plunger over the next 24 hours.
- 7. If a new infusion set is being used it should be inserted into the site by grasping the skin firmly and pushing the butterfly needle into the subcutaneous tissue at a 45-degree angle. The skin is released and the butterfly is secured in position with a clear film dressing.
- 8. The start button can now be pressed, the transparent cover placed on the driver and the device placed in a safe, convenient place next to the patient. A fabric bag with a drawstring opening is often used to conceal the driver in a discrete fashion.

# Monitoring

The infusion site should be checked regularly, e.g. every 4 hours, and observed for viability, skin reactions or leakage. The driver should also be checked to ensure that it is functioning correctly and there is no sign of precipitation in the syringe.

Because of minor variations the accuracy of syringe driver infusion rates, the driver should be checked at least 1 hour before the anticipated finish of the infusion to check that a replacement is not required.

Drivers should be cleaned after each use with a disposable cloth dampened with a mild detergent. They should be calibrated annually.

### Troubleshooting

If the infusion has finished early this may indicate that:<sup>1</sup>

- The rate was incorrectly set.
- · The scale length was measured incorrectly.
- The line was primed after the syringe was measured.

If the infusion finishes late this may indicate that:

- The rate was incorrectly set.
- The scale length was measured incorrectly.

If the infusion has stopped this may indicate that:

- The line is blocked.
- The battery is exhausted.
- There is precipitation.
- · The infusion site has become inflamed.
- The syringe has not been correctly fitted to the driver.

# Appendix 10 Ideal bodyweight, dosing in patients with renal or hepatic impairment

# Ideal bodyweight (IBW)

For the dosing of some drugs and for calculation of creatinine, ideal bodyweight rather than actual bodyweight is used. This can be calculated as follows:<sup>1</sup>

| For men :   | IBW $(kg) = 50$ | kg + 2.3 | kg for | each | inch | over | 5 feet. |
|-------------|-----------------|----------|--------|------|------|------|---------|
| For women : | IBW $(kg) = 49$ | kg + 1.7 | kg for | each | inch | over | 5 feet. |

If one wishes to obtain an approximately similar answer using only a metric measure of height, utilise the following equations:

For men : IBW  $(kg) = 50 \ kg + 0.9 \ kg$  for each cm of height over 152 cm. For women : IBW  $(kg) = 49 \ kg + 0.7 \ kg$  for each cm of height over 152 cm.

## Dose adjustment in impaired renal function

If a drug is excreted from the body mainly by the kidneys then any reduction in renal function potentially means that the drug is not cleared at the same rate as would be expected in normal renal function. The drug might therefore accumulate in the body, potentially resulting in serious adverse effects. In order to prevent this, the dose should be adjusted or the drug avoided altogether if necessary. The monographs in this book give some guidance on this but specialist texts such as *The Renal Drug Handbook* should be consulted if necessary.<sup>2</sup> The degree of renal impairment is defined by the patient's creatinine clearance (CrCl), which is closely related to an individual's actual glomerular filtration rate (GFR). Some hospitals calculate an estimate of the glomerular filtration rate (eGFR) and it is acceptable in practice to use this figure as a substitute for creatinine clearance if available, except for patients at extremes of bodyweight or for drugs with a narrow therapeutic range.

In the absence of an eGFR value, the patient's creatinine clearance may be calculated using the Cockcroft and Gault equation.<sup>3</sup> For this the following patient-specific information is needed:

• Sex

Serum creatinine level in micromol/L (should be relatively stable)

Height – to calculate ideal bodyweight (IBW) if necessary.

 $Creatinine \ clearance \ (mL/minute) = \frac{F \times (140 - age) \times weight \ (kg)^{\star}}{Serum \ creatinine \ (micromol/L)}$ 

where F = 1.23 for a male; 1.04 for a female.

\*If a patient is obese, use ideal bodyweight (IBW) because fatty tissue does not produce creatinine (for the purposes of the calculation, obesity is typically classified as actual bodyweight >120% of IBW).

<sup>•</sup> Age

## Dose adjustment in impaired liver function

Drugs metabolised or excreted by the liver may accumulate in the body if liver function is impaired. Doses should be adjusted or the drug avoided altogether if necessary. The monographs in this book give some guidance on this, but determining the degree of hepatic impairment is much more difficult than with renal function. Several methods exist but the most commonly used is the Child–Pugh classification,<sup>4</sup> which has been developed as a prognostic tool in chronic liver disease.

For the Child–Pugh classification, five clinical measures of liver disease are given scores of 1, 2 or 3 points in increasing severity as shown in Table A10.1. The scores for each parameter are added together and the degree of hepatic impairment is categorised as Child–Pugh class A to C as follows:

- 5–6 points Class A
- 7-9 points Class B
- 10–15 points Class C

| Table A10.1         Scoring system for Child-Pugh classification of hepatic impairment |                |                                            |                                 |
|----------------------------------------------------------------------------------------|----------------|--------------------------------------------|---------------------------------|
| Measure                                                                                | Scores 1 point | Scores 2 points                            | Scores 3 points                 |
| Bilirubin - total (micromol/L or<br>mg/dL)                                             | <34° (<2)      | 34-50° (2-3)                               | >50 (>3)                        |
| Serum albumin (g/L)                                                                    | >35            | 28-35                                      | <28                             |
| INR<br><i>or</i> prothrombin time (seconds)                                            | <1.7<br>1-3    | 1.7-2.3<br>4-6                             | >2.3<br>>6                      |
| Ascites                                                                                | None           | Moderate or suppressed with medication     | Refractory                      |
| Hepatic encephalopathy                                                                 | None           | Grade I-II (or suppressed with medication) | Grade III-IV (or<br>refractory) |

<sup>a</sup> In primary sclerosing cholangitis and primary biliary cirrhosis, the bilirubin reference ranges are increased to <68 micromol/L (<4 mg/dL) for 1 point and 68-170 micromol/L for 2 points (4-10 mg/dL).

For the purposes of certain monographs this classification is all that may be needed. As a prognostic tool, however, the classification is used by clinicians to determine the survival chances of a patient.

# Appendix 11 Risk ratings

The risk ratings included in the *Injectable Drugs Guide* monographs are based on the NPSA tool for risk assessment of individual injectable medicine products prepared in clinical areas (see www.npsa.nhs. uk/health/alerts).

The risk scores are presented as a grid displaying pictorial icons for the individual risk category and the score is the summation of these categories. The eight risk categories are:

**Therapeutic risk**: where there is a significant risk of patient harm if the injectable medicine is not used as intended. This risk is symbolised by skull and crossbones.

**Use of a concentrate:** where further dilution after reconstitution is required before use, i.e. slow intravenous injection is not appropriate. This risk is symbolised by a bottle of a concentrated solution.

**Complex calculation:** any calculation with more than one step required for preparation and/or administration, e.g. micrograms/kg/hour, dose unit conversion such as mg to mmol or % to mg. This risk is symbolised by a calculator.

**Complex method:** where more than five non-touch manipulations are involved, or other steps including syringe-to-syringe transfer, preparation of a burette, the use of a filter. This risk is symbolised by a chain showing several links.

**Reconstitution of powder in a vial:** where a dry powder has to be reconstituted with a liquid. This risk is symbolised by a liquid being injected into a vial of dry powder.

Use of a part vial or ampoule, or use of more than one vial or ampoule is **required**: e.g. 5 mL is required from a 10-mL vial, or four 5-mL ampoules are required for a single dose. This risk is symbolised by showing more than one vial with the second vial only half used.

**Use of a pump or syringe driver:** all pumps and syringe drivers require some element of calculation and therefore have potential for error; and the potential risk is considered less significant than the risks associated with **not** using a pump when indicated. This risk is symbolised by a syringe pump.

**Use of non-standard giving set/device required:** examples include light-protected products, low adsorption, use of an in-line filter or air inlet. This risk is symbolised by a square peg in a round hole to indicate something of a non-standard nature.

A **traffic light system** is used to denote broad risk banding together with a standard phrase to aid prioritisation for risk management in any given clinical area:

- RED: Six or more risk factors: high-risk product Risk-reduction strategies are required to minimise these risks.
- **AMBER:** Three to five risk factors: moderate-risk product *Risk-reduction strategies are recommended.*
- GREEN: Zero to two risk factors: lower-risk product Risk-reduction strategies should be considered.

NB: Although NPSA risk ratings only assess these eight categories, risk-reduction strategies could still be employed outside of these categories to further reduce risks in clinical areas; for example, staff training or standard operating procedures that could make even a zero-rated product safer to use.

It is possible that the risk score may vary depending on the method of administration; for example, a direct intravenous injection may score lower than an infusion as there is no further dilution involved and therefore one less risk factor. In these scenarios the risk rating at the end of each monograph is always for the highest rated assessment unless otherwise stated.

It is vital that a local risk assessment accounts for method of administration in any given clinical area, so the risk score may be moderated to reflect local practice.

In all areas, appropriate competence is essential for healthcare professionals working with injectable medicines to give assurance of safety. Local policies and procedures must be adhered to but individuals should also include injectable therapy in their continuing professional development. The BMJ learning website provides such an opportunity with a free module on injectable medicines (accessible at http://learning.bmj.com/learning/search-result.html?moduleId=10009161) and this is strongly recommended.
