Monographs

Abciximab
Acetylcysteine
Aciclovir (acyclovir)
Adalimumab
Adenosine
Adrenaline (epinephrine)
Alfacalcidol
Alteplase
Amikacin
Aminophylline
Amiodarone hydrochloride
Amoxicillin (amoxycillin)
Amphotericin (amphotericin B)
Ampicillin
Anidulafungin
Apomorphine hydrochloride
Aripiprazole
Ascorbic acid (vitamin C)
Atenolol
Atosiban
Atropine sulfate
Azathioprine
Aztreonam

ix	Bemiparin sodium	78
	Benzatropine mesilate	
х	(benztropine mesylate)	81

Preface

The *Injectable Drugs Guide* provides a user-friendly, single point of reference for healthcare professionals in the prescribing, preparation, administration and monitoring of injectable medicines.

The idea for such a book grew out from some of the entries in our sister book *Clinical Pharmacy Pocket Companion,* which, as well as covering many clinical topics such as electrolyte disturbances and perioperative management of medicines, also deals with a number of medicines requiring therapeutic monitoring. It became apparent that the benefits of such an approach could be rolled out to a greater number of medicines. At around the same time the UK National Patient Safety Agency issued a patient safety alert entitled 'Promoting safer use of injectable medicines' (NPSA/2007/20). This requires organisations to risk assess individual parenteral drugs and put procedures in place to allow them to be handled more safely.

The *Injectable Drugs Guide* is a handbook supporting the risk assessment process (each drug has a risk rating). It also provides a holistic approach to injectable medicines to meet the needs of the many disciplines involved in the clinical use of injectables and also those providing advice about injectable drug use.

The book comprises primarily individual drug monographs. There are a number of appendices giving further guidance on specific aspects of injectable therapy and additional clinical information (the full list of these is found on the Contents page).

In the main, cancer chemotherapy agents are not covered in the monographs. This is because there are tight controls around the use of these agents in clinical practice. Their handling in clinical settings is highly protocol driven and locality specific; use by inexperienced individuals is inappropriate.

> Alistair Gray Jane Wright Vince Goodey Lynn Bruce November 2010

How to use the Injectable Drugs Guide monographs

Each monograph is presented in a format that sequences the information as needed by healthcare professionals from *contemplation* of treatment, through preparation and administration, to the monitoring that may be required during and after therapy. Monographs are generally presented in the following order:

Drug name and form(s) of the preparation(s)

Background information about each medicine including,

- · Type of drug
- What it is used to treat (licensed and unlicensed indications and routes)
- · Additional miscellany of interest to the user
- · If appropriate, how doses of the drug are usually expressed

Pre-treatment checks including,

- · Contraindications and cautions to be considered prior to use
- Any measures and/or tests that should be undertaken before commencing therapy. In some cases these tests are mandatory; in others they are dependent on the circumstances in which the drug is being used. These are listed alphabetically.
- Pregnancy and breast-feeding information has not been included except in a few special cases (standard reference sources or the advice of a Medicines Information department should be sought if this information is needed).

Dose including indication-specific information and any adjustments required in renal or hepatic impairment. Unless otherwise stated, doses are for adults (child and neonatal doses have not been included).

Routes of administration

- A series of headings outline the route(s) by which a particular drug may be given; the specifics of preparation and administration are provided for each route. In some cases the individual heading indicates the circumstances in which a particular route is appropriate.
- For drugs given by infusion, most monographs specify the quantity of infusion fluid to use. However, some monographs use the phrase 'dilute in a suitable volume of compatible infusion fluid'. In this case the prescriber should choose a volume and fluid that is appropriate to the patient's needs and clinical condition (compatibility data are given further down the monograph in the Technical Information table).

Technical information includes details of:

- **Incompatibilities** with fluids, other drugs by Y-site administration and also sometimes with materials
- **Compatibilities** with infusion fluids and also drugs where co-administration and concentrations are likely to be used in practice. Drugs for which compatibility is concentration-specific are *not* included in this list. More detailed sources such as Trissel¹ should be used to clarify these.
- **pH**, particularly for drugs which are given intravenously
- **Sodium content** is stated if it is ≥1 mmol per likely dose; information about other significant electrolytes is given where appropriate
- · Osmolarity for the most significantly hyperosmolar products
- **Excipients** where allergy is a possibility or where these could have significant sideeffects in certain individuals
- **Storage conditions** advised for long-term and in-use storage plus, in some cases details on the significance of any change in appearance
- Displacement value for dry powder products
- Special handling and management of spillage information if appropriate
- **Stability after preparation information.** This is *not* provided so that infusions can be prepared significantly prior to use in a clinical area, but rather to indicate how long a preparation is stable if it is not possible to administer it immediately. Stability information is also provided for reconstituted multidose vials.

Monitoring includes the measures required to ensure the medicine is used safely throughout therapy, the clinical outcome and other parameters that need consideration, e.g. certain adverse effects. The frequency of monitoring of each parameter is stated and the rationale for monitoring. In some cases the frequency is precise, e.g. 'daily', in others the frequency is not clearly defined in the literature and an individual clinician will need to decide what is reasonable. In these cases the term 'periodically' has been used.

Additional information includes

Common and serious undesirable effects including:

- Immediate adverse reactions or those that may occur shortly after administration
- **Injection- or infusion-related** adverse events, either due to rapid administration or those which are injection-site related
- Other adverse reactions

Pharmacokinetics in the main provides an indication of the elimination half-life of the drug, which can be useful in determining duration of effect. Some monographs provide information on other pharmacokinetic or pharmacodynamic parameters where these might be helpful.

Significant interactions drugs are grouped together under subheadings to give an indication of likely effect of the interaction. These lists are not comprehensive and more detailed sources such as *Stockley's Drug Interactions*² should be used if required.

Action in case of overdose gives guidance on managing *therapeutic* overdose of the drug and in most cases lists general supportive measures required. For the management of significant overdose an on-line source such as Toxbase³ should always be consulted. **Counselling** points are intended to provide a prompt for healthcare professionals as they speak to patients about their therapy.

Risk rating. Each medicine has been risk-assessed, considering the worst case scenario, to provide an overall risk rating based on the NPSA tool for risk assessment of individual injectable medicine products prepared in clinical areas.⁴ The assessment is displayed pictorially with icons and as a risk score. See Appendix 11 for more information on the risk rating used.

References. In general the main reference source used to assemble the information has been the manufacturer's product literature (in the UK this is the Summary of Product Characteristics or SPC) and MedicinesComplete (see below). In the main, SPCs mentioned can be accessed on-line at http://www.medicines.org.uk/EMC/. To save space references have not been included if information has been sourced from MedicinesComplete, although the SPCs used have been stated for clarity. Any other reference source used is stated in the normal way using the Vancouver system of referencing.

Feedback

Feedback on any aspect of the book would be welcome via the e-mail address pharmpresseditorial@rpharms.com.

About the authors

Lynn Bruce studied pharmacy at Aston University. The first 20 years of her working life were based in secondary care variously as MI pharmacist, clinical pharmacy lead, clinical economist and latterly in various management positions. She migrated across the divide to primary care in 1997 becoming PCG and then PCT prescribing advisor. Hospital clinical pharmacy beckoned her back to secondary care in 2002: she is now Pharmacy Team Leader on the Medical Assessment Unit at the Royal Blackburn Hospital.

Lynn is married and, when she's not writing pharmacy books, loves studying wildlife and travelling and is addicted to puzzles of all types.

Vince Goodey graduated in 1985 from the London School of Pharmacy, and has since worked primarily in the hospital sector in clinical and managerial roles. As a postgraduate Vince studied at the University of Manchester to attain an MSc in Pharmacy Practice in 1996.

Although hailing originally from Essex, Vince is currently Deputy Director of Pharmacy at East Lancashire Hospitals NHS Trust.

Alistair Gray is from Sunderland. He studied pharmacy at Sunderland Polytechnic, graduating in 1988 with first-class honours, and then completed his pre-registration year with Boots in Newcastle-upon-Tyne. He continued working for Boots in a variety of pharmacy and store management positions in the North West of England. In 2002 he changed disciplines and became Community Services pharmacist at Queens Park Hospital in Blackburn. He completed a Diploma in Clinical & Health Services Pharmacy at the University of Manchester in 2008 and subsequently became Clinical Services Lead Pharmacist for East Lancashire Hospitals NHS Trust in 2009 based at the now re-named Royal Blackburn Hospital.

Alistair is married with two children and loves spending time with his family. He follows Formula One motor racing closely, enjoys reading, eating out, going to the movies, playing guitar and songwriting.

Jane Wright, after working for 18 years in the Civil Service, attended the University of Manchester to study pharmacy. Jane graduated in 1994 and did her pre-registration year at the Royal Preston Hospital. For the next ten years Jane worked in Blackburn hospitals in a variety of clinical roles, her last being Clinical Services Manager with responsibility for education and training. In 1999 she obtained a Diploma in Clinical & Health Services Pharmacy at the University of Manchester. She moved to Lancashire Care NHS Foundation Trust in April 2005 where she is currently employed as Lead Pharmacist for East Lancashire.

Jane is married and in her spare time enjoys playing with Molly and Polly (two very lively dogs).

Contributors

Catherine Strong MRPharmS DipClinPharm, Lead Clinical Pharmacist (acute medicine) based at Fairfield General Hospital (The Pennine Acute Hospitals NHS Trust), Bury, UK.

Katy Hand BSc(Hons) MRPharmS MSc in Clinical Pharmacy, Critical Care Pharmacist, Southampton General Hospital, Southampton, UK.

Kevin Johnson MRPharmS DipClinPharm, Medical Admissions Unit Pharmacist, Royal Blackburn Hospital, Blackburn, UK.

Joanna Wallett MRPharmS DipClinPharm, Senior Clinical Pharmacist, East Lancashire Hospitals NHS Trust, Royal Blackburn Hospital, Blackburn, UK.

Acknowledgements

All the authors would like to thank Cat, Katie, Joanna and Kevin (our contributors) for all their time, expertise and patience.

The advice and assistance provided by Sue Keeling and the pharmacy department of the Imperial College Healthcare NHS Trust and the pharmacy departments of Epsom and St Helier University Hospitals NHS Trust in producing the guidelines in the appendices is gratefully acknowledged.

The advice and assistance provided by the National Extravasation Information Service in producing Appendix 6 is gratefully acknowledged. Thanks also to Bruce Burnett who put the original draft of Appendix 6 and Appendix 7 together for the *Clinical Pharmacy Pocket Companion*.

We would like to acknowledge our respective employers: East Lancashire Hospitals NHS Trust and Lancashire Care NHS Foundation Trust.

Alistair thanks Rachel, Amelia and Imogen for all their support throughout the creation of this publication. It took just a little bit longer than expected!

Jane thanks Steve for his tolerance, and apologies to Molly and Polly for all the missed walkies opportunities.

Lynn thanks John for scraping her off the ceiling during moments of stress.

Vince thanks Joanne and Josh for their support and Marm for all her wellintentioned but aberrant key padding.

Finally we would like to thank everyone at the Pharmaceutical Press who has had a hand in this publication, particularly Christina De Bono, Louise McIndoe, Rebecca Perry and Linda Paulus.

VTE	venous thromboembolism
WCC	white cell count
WFI	water for injections
WPW	Wolff-Parkinson-White syndrome

Abciximab

2 mg/mL solution in 5-mL vials

- Abciximab is a platelet aggregation inhibitor of the glycoprotein (GP IIb/IIIa) receptor inhibitor class.
- It is used to prevent ischaemic cardiac complications in patients undergoing PCI and for shortterm prevention of MI in patients with unstable angina not responding to conventional treatment and who are scheduled for PCI.

Pre-treatment checks

- Avoid in active internal bleeding; major surgery, intracranial or intraspinal surgery or trauma within the past 2 months; stroke within the past 2 years; intracranial neoplasm, arteriovenous malformation or aneurysm, severe *†BP*, haemorrhagic diathesis, thrombocytopenia, vasculitis, hypertensive retinopathy; breast feeding.
- Caution with concomitant use of drugs that ↑ risk of bleeding, in elderly patients; in hepatic and renal impairment; and in pregnancy.
- The number of vascular punctures and IM injections should be minimised during the treatment.
- IV access should be obtained only at compressible sites of the body.
- All vascular puncture sites should be documented and monitored closely (caution if there is puncture of non-compressible vessels within 24 hours).
- The use of urinary catheters, nasotracheal intubation and nasogastric tubes should be critically considered before commencing therapy.

Biochemical and other tests

ACT	FBC (including platelets, Hb and haematocrit)
APTT	LFTs
Blood pressure and pulse	Prothrombin time
Bodyweight	Renal function: U, Cr, CrCl (or eGFR)
ECG	

Dose

Abciximab is used in combination with aspirin and heparin.

Standard dose: initially 0.25 microgram/kg by IV injection over 1 minute, followed immediately by IV infusion at a rate of 0.125 microgram/kg/minute (maximum 10 micrograms/minute).

For prevention of ischaemic complications: start 10–60 minutes before PCI and continue infusion for 12 hours.

For unstable angina: start up to 24 hours before possible PCI and continue infusion for 12 hours after intervention.

Concomitant aspirin therapy: at least 300 mg daily.

Concomitant therapy with unfractionated heparin

- Before and during PCI: see product literature for details.
- *Unstable angina:* heparin is given by IV infusion throughout the abciximab infusion to maintain APTT at 60–85 seconds.

Dose in renal impairment: use with caution in severe impairment: *†risk of bleeding.* **Dose in hepatic impairment:** avoid in severe impairment: *†risk of bleeding.*

Intravenous injection

Preparation and administration

- 1. Do not shake the vial.
- 2. Withdraw the required dose.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration before administration and discard if present.
- 4. Give by IV injection over 1 minute through a non-pyrogenic low-protein-binding 0.2-, 0.22- or 5.0-micron filter.

Continuous intravenous infusion

Preparation and administration

*Filter either at the preparation or at the administration stage.

- 1. Do not shake the vial.
- 2. Withdraw the required dose and add to a suitable volume of NaCl 0.9% or Gluc 5% through a nonpyrogenic low-protein-binding 0.2-, 0.22- or 5-micron filter*. Mix well.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration before administration and discard if present.
- 4. Give at the calculated rate via a volumetric infusion device through an in-line non-pyrogenic lowprotein-binding 0.2- or 0.22-micron filter* (if not filtered at the preparation stage).

Technical information		
Incompatible with	No information	
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5% Y-site: Adenosine, atropine sulfate, bivalirudin, fentanyl, metoprolol, midazolam	
рН	7.2	
Sodium content	Negligible	
Storage	Store at 2-8°C in original packaging. Do not freeze. Do not shake.	
Stability after preparation	From a microbiological point of view, should be used immediately; however, prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours.	

Monitoring

Measure	Frequency	Rationale
ACT	Every 30 minutes and a minimum of 2 minutes after each <i>heparin</i> bolus	 If the ACT is <200 seconds, additional heparin boluses of 20 units/kg may be given until an ACT ≥200 seconds is achieved. If higher doses of heparin are considered clinically necessary (despite a greater bleeding risk), the heparin can be carefully titrated using weightadjusted boluses to a target ACT not exceeding 300 seconds.

Abciximab | 3

Monitoring (continued)					
Measure	Frequ	lency	Rationale		
Platelets	2-4 hours after the initial dose and at 24 hours		 Thrombocytopenia may occur. If platelets drop to: 60 000 cells/mm³ (60 × 10°/L), heparin and aspirin should be stopped. <50 000 cells/mm³ (50 × 10°/L), transfusion of platelets should be considered. <20 000 cells/mm³ (20 × 10°/L), platelets should be transfused. 		
Hb and haematocrit	12 an dose	d 24 hours after bolus	• To check for any adverse events or bleeding.		
ECG	Shortly after catheterisation and 24 hours after bolus dose				
Vital signs (including BP and pulse)	Hourly for the first 4 hours, and then at 6, 12, 18, and 24 hours after bolus dose				
Additional information					
Common and serious Imme undesirable effects Comm punct		Immediate: Anaphylaxi reported. <i>Common:</i> Thrombocyto puncture-site pain, back	mmediate: Anaphylaxis and other hypersensitivity reactions have rarely been eported. <i>Common:</i> Thrombocytopenia, ↓pulse, nausea, vomiting, chest pain, pyrexia, suncture-site pain, back pain, headache, bleeding, ↓BP.		
Pharmacokineti	cs	Initial elimination half-life is 10 minutes, followed by a second phase of about 30 minutes.			
Significant interactions		 The following may <i>îabciximab</i> levels or effect (or <i>îside-effects</i>): thrombolytics, coumarin anticoagulants, antiplatelet drugs. 			
Action in case of overdose		Symptoms to watch for: Allergy, thrombocytopenia or uncontrolled bleeding. Antidote: No specific antidote. Stop administration and give supportive therapy as appropriate, including platelet transfusion if necessary.			
Counselling		Administration may result in the formation of human anti-chimeric antibody (HACA), which could potentially cause allergic or hypersensitivity reactions (including anaphylaxis), thrombocytopenia, or diminished benefit upon re- administration.			
Risk rating: RED		Score = 6 High-risk product: Risk	reduction strategies are required to minimise these risks.		
	H				

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Bibliography

SPC Reopro 2 mg/mL solution for injection or infusion (accessed 30 March 2010).

Acetylcysteine

200 mg/mL solution in 10-mL ampoules (20% solution)

- Acetylcysteine is used for the prevention of hepatotoxicity in the treatment of paracetamol (acetaminophen) overdosage.
- It protects the liver if infused within 24 hours of paracetamol ingestion. It is most effective if given within 8 hours of ingestion, after which effectiveness declines sharply.
- If more than 24 hours have elapsed since ingestion, advice should be sought from the National Poisons Information Service (NPIS) or from a liver unit on the management of serious liver damage.
- · Acetylcysteine can be nebulised (unlicensed) for use as a mucolytic.

Pre-treatment checks

- Administer with caution to any patient with asthma or a history of bronchospasm or peptic ulcer disease (*†risk* of GI haemorrhage). However, do not delay necessary treatment in these patients.
- Previous anaphylactoid reaction to acetylcysteine is *not* an absolute contraindication for a further treatment course: NPIS advice is to pretreat with an antihistamine, e.g. chlorphenamine 10 mg IV.
- In pregnancy, appropriate maternal treatment is important for the wellbeing of both the mother and the fetus. If the blood levels of paracetamol indicate that acetylcysteine is required, it should be given.

Biochemical and other tests (not all are necessary in an emergency situation)

Bodyweight INR LFTs

The plasma paracetamol concentration in relation to time after overdose is used to determine whether a patient is at risk of hepatotoxicity and should therefore receive acetylcysteine.

As there is a risk of increased acetylcysteine side-effects, it is unwise to institute treatment before paracetamol levels are known unless more than 8 hours have elapsed since ingestion or levels are likely to be delayed.

NB: Blood samples taken <4 hours after a paracetamol overdose give unreliable estimates of the serum paracetamol concentration.

Refer to the poisoning treatment graph (Figure A1) at the end of the monograph:

- Otherwise healthy patients whose plasma paracetamol concentrations fall on or above the 'Normal treatment line' should receive acetylcysteine. If there is doubt about the timing of the overdose, consideration should be given to treatment with acetylcysteine.
- Sufferers from chronic alcoholism and patients taking enzyme-inducing drugs, e.g. phenytoin, phenobarbital, primidone, carbamazepine, rifampicin and St John's wort, are susceptible to paracetamol-induced hepatotoxicity at lower plasma paracetamol concentrations and should be treated if plasma paracetamol concentrations fall on or above the 'High-risk treatment line'.
- The 'High-risk treatment line' should also be used to guide treatment in patients with malnutrition, e.g. patients with anorexia or AIDS, as they are likely to have depleted glutathione reserves.
- In patients who have taken staggered overdoses, blood levels are meaningless in relation to the treatment graph, and these patients should be considered for treatment with acetylcysteine.

Dose

It is essential to consult a poisons information service, e.g. Toxbase at www.toxbase.org (password or registration required) for full details of the management of paracetamol toxicity.

Treatment for paracetamol poisoning by IV infusion (refer to Table A1 below):

Bag 1: 150 mg/kg bodyweight given in 200 mL of infusion fluid over 15 minutes

Bag 2: 50 mg/kg bodyweight in 500 mL infusion fluid over the next 4 hours

Bag 3: 100 mg/kg bodyweight in 1 L infusion fluid over the next 16 hours

Treatment for paracetamol poisoning by the oral route (unlicensed): in the USA, acetylcysteine is licensed for oral use in paracetamol overdose. An initial dose of 140 mg/kg as a 5% solution is followed by 70 mg/kg every 4 hours for an additional 17 doses.

As a mucolytic via nebuliser (unlicensed): the adult dose is 3–5 mL acetylcysteine 20% injection, nebulised 3–4 times daily using air (use of concentrated oxygen causes degradation).

Acetylcysteine may cause bronchospasm. This can be avoided either by giving a lower dose – diluting 1 mL acetylcysteine 20% in 5 mL NaCl 0.9% and giving 3–4 mL – or pre-administering a nebulised bronchodilator.

Intravenous infusion

Preparation and administration

- 1. Withdraw the required dose and add to the appropriate volume of infusion fluid. Mix well.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration before administration.
- 3. Give by IV infusion over the time period stated above.

Oral administration (unlicensed)

Preparation and administration

- 1. Withdraw the required dose.
- 2. Dilute the injection to 4 times its volume with diet soft drink and give to the patient to drink; if given via a nasogastric tube, water may be used as the diluent.

Nebulisation (unlicensed)

Preparation and administration

- 1. Withdraw the required dose and dilute with NaCl 0.9% if required (see dose above).
- 2. Give via a nebuliser using air (not oxygen).

Technical information				
Incompatible with	Equipment made of rubber and some metals, e.g. iron, copper and nickel. Otherwise no information.			
Compatible with	Equipment made of plastic, glass and stainless steel. Flush: NaCl 0.9% Solutions: Gluc 5% (preferred), NaCl 0.9% (both including added KCl) Y-site: No information			
рН	6-7.5			
Sodium content	12.8 mmol/10 mL			

(continued)

6 Acetylcysteine

Technical information (continued)				
Storage	Store below 25°C. A change in colour to light purple is not thought to indicate significant impairment of safety or efficacy.			
Stability after preparation	From a microbiological point of view, prepared infusions should be used immediately; however, solutions are known to be stable at room temperature for up to 24 hours.			

Monitoring

Measure	Frequency	Rationale
Liver function and INR	To determine completion of antidote	 ↑Transaminases (ALT or AST) and ↑INR indicate hepatotoxicity. Acetylcysteine can also cause a marginally elevated INR. An INR of ≤1.3 with normal transaminases does not warrant further treatment. If all measures are raised, then 'bag 3' should be repeated over 16 hours.
ECG	If indicated	 ECG changes have been reported in patients with paracetamol poisoning, irrespective of the treatment given.
Renal function and serum K		 ↓K has been reported in patients with paracetamol poisoning, irrespective of the treatment given. Renal failure is a recognised complication of paracetamol overdose.
Serum bicarbonate		 Metabolic acidosis can be a complication of paracetamol overdose.

Additional infor	mation
Common and serious undesirable effects	 Immediate: Anaphylactoid or hypersensitivity-like reactions have been reported in 0.3-3% of patients, in patients with hepatic cirrhosis, and in patients with low or absent paracetamol concentrations. Symptoms include nausea/vomiting, injection-site reactions, flushing, itching, rashes/utricaria, angioedema, bronchospasm/respiratory distress, ↓BP and, rarely, ↑pulse or ↑BP. These have usually occurred 15-60 minutes after the start of infusion. Symptoms have often been relieved by stopping the infusion, but occasionally an antihistamine or corticosteroid may be necessary. Once the reaction has settled, the infusion can normally be restarted at 50 mg/kg over 4 hours. Further reactions are almost unknown. Infusion-related: Too rapid administration: Higher incidence of hypersensitivity reactions.
Pharmacokinetics	Elimination half-life of 2-6 hours reported after IV dosing, with 20-30% of the administered dose being recovered unchanged in the urine.
Significant interactions	No known interactions.
Action in case of overdose	<i>Symptoms to watch for:</i> effects similar to the anaphylactoid reactions noted above, but they may be more severe. There is a theoretical risk of hepatic encephalopathy.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Bibliography

SPC Parvolex (accessed 17 August 2008). Toxbase at www.toxbase.org (accessed 18 August 2008).

Figure A1 Patients whose plasma paracetamol concentrations are above the normal treatment line should be treated with acetylcysteine by IV infusion (or, if acetylcysteine cannot be used, with methionine by mouth, provided the overdose has been taken within 10-12 hours and the patient is not vomiting).

Patients on enzyme-inducing drugs (e.g. carbamazepine, phenobarbital, phenytoin, primidone, rifampicin, alcohol and St John's wort) or who are malnourished (e.g. in anorexia, in alcoholism, or those who are HIV positive) should be treated if their plasma paracetamol concentration is above the high-risk treatment line.

The prognostic accuracy after 15 hours is uncertain, but a plasma paracetamol concentration above the relevant treatment line should be regarded as carrying a serious risk of liver damage.

 Table A1
 Acetylcysteine dosing table for paracetamol overdose (continued)

Aciclovir (acyclovir)

25 mg/mL solution in 10-mL, 20-mL and 40-mL vials; 250-mg and 500-mg dry powder vials

- Aciclovir sodium is a synthetic purine nucleoside analogue structurally related to guanine.
- It is used mainly for the treatment of viral infections due to herpes simplex virus (types 1 and 2) and varicella-zoster virus (herpes zoster and chickenpox).
- Doses are expressed in terms of the base: Aciclovir $1 g \cong 1.1 g$ aciclovir sodium.

Pre-treatment checks

- Check that the patient is not hypersensitive to aciclovir or valaciclovir; caution in patients with neurological abnormalities or substantial hypoxia.
- Hydration status (patient **must** be adequately hydrated).

Biochemical and other tests

Bodyweight	LFTs
FBC	Renal function: U, Cr, CrCl (or eGFR)

Dose

To avoid excessive dosing, doses should be calculated on the basis of ideal bodyweight (IBW) in obese patients. See Appendix 10.

Treatment of herpes simplex in immunocompromised patients, severe initial genital herpes, and varicella-zoster: 5 mg/kg by IV infusion every 8 hours, usually for 5 days. **Treatment of varicella-zoster in immunocompromised patients and simplex encepha-litis:** 10 mg/kg by IV infusion every 8 hours (usually for at least 10 days in encephalitis). **Prophylaxis of herpes simplex in immunocompromised patients:** 5 mg/kg by IV infusion every 8 hours.

Dose in renal impairment: adjusted according to creatinine clearance:

- CrCl >25-50 mL/minute: 5-10 mg/kg every 12 hours.
- CrCl 10-25 mL/minute: 5-10 mg/kg every 24 hours.
- CrCl <10 mL/minute: 2.5-5 mg/kg every 24 hours.

Intermittent intravenous infusion

Preparation and administration

See Special handling below.

- If using dry powder vials, reconstitute each 250-mg vial with 10 mL WFI (use 20 mL for each 500mg vial). Shake gently to dissolve to give a solution containing 25 mg/mL.
- 2. Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually NaCl 0.9%). The final concentration must be no more than 5 mg/mL (i.e. add doses \leq 500 mg to 100 mL; add doses >500 mg to 250 mL).
- 3. The solution should be clear, light yellow and slightly opalescent. Inspect visually for particulate matter or discoloration before administration and discard if present.
- 4. Give by IV infusion over a minimum of 1 hour.

Intermittent intravenous infusion via a syringe pump

Preparation and administration

See Special handling in the table below.

- 1. If using dry powder vials, reconstitute each 250-mg vial with 10 mL WFI or NaCl 0.9% (use 20 mL for each 500-mg vial). Shake gently to dissolve to give a solution containing 25 mg/mL.
- 2. Withdraw the required dose into a syringe pump without further dilution.
- The solution should be clear, light yellow and slightly opalescent. Inspect visually for particulate matter or discoloration before administration and discard if present.
- Give by IV infusion over a minimum of 1 hour. Periodically inspect for turbidity or crystallisation; discard if present.

Technical information					
Incompatible with	WFI containing parabens or benzyl alcohol. Aztreonam, cisatracurium, dobutamine, dopamine, foscarnet, levofloxacin, meropenem, morphine sulfate, ondansetron, pantoprazole, pethidine, piperacillin with tazobactam, tramadol.				
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, Gluc-NaCl, Hartmann's (including added KCl) Y-site: Amikacin, ampicillin, benzylpenicillin, cefotaxime, ceftazidime, ceftriaxone, cefuroxime, chloramphenicol sodium succinate, clindamycin, co- trimoxazole, dexamethasone, erythromycin, fluconazole, gentamicin, granisetron, hydrocortisone sodium succinate, imipenem with cilastatin, magnesium sulfate, methylprednisolone sodium succinate, metoclopramide, metronidazole, propofol, ranitidine, remifentanil, tobramycin, vancomycin				
рН	11				
Sodium content	About 1.1 mmol/250-mg vial.				
Storage	Store below 25 $^{\circ}\text{C}$ in original packaging. Do not refrigerate (may precipitate).				
Special handling	Avoid contact with eyes and unprotected skin.				
Stability after reconstitution	From a microbiological point of view, should be used immediately; however, prepared infusions may be stored at 25°C and infused within 12 hours. Check for signs of precipitation.				
Monitoring					
Measure	Frequency	Rationale			
U&Es, serum creatinine	After initiation, then periodically	 Urea and creatinine levels may transiently rise. If serious, they are usually reversed by rapid rehydration, dose reduction or withdrawal. 			
LFTs	Periodically	• Reversible increases in liver-related enzymes may occur.			
FBC	 Anaemia, thrombocytopenia and leucopenia h been reported (rarely). 				

12 | Aciclovir

Monitoring (continued)					
Measure	Frequency	Rationale			
Signs and symptoms of encephalopathy	On presentation	 Typical symptoms include lethargy, obtundation, tremors, confusion, hallucinations, agitation, seizures and coma. They are usually reversible. 			
Additional infor	mation				
Common and serious ur	ndesirable effects	Infusion-related: Local: Inflammation or phlebitis at infusion site. Other: Headache, nausea, vomiting, diarrhoea, rash, pruritus, urticaria.			
Pharmacokinetics		Elimination half-life is 3.8 hours in normal adults (19.5 hours if CrCl $<\!15mL/minute$).			
Significant interactions		No significant interactions.			
Action in case of overde	ose	Symptoms to watch for: Aciclovir crystals may precipitate in renal tubules, causing renal tubular damage, if the maximum solubility of free aciclovir is exceeded. Maximum urine concentration occurs within the first few hours of infusion; therefore, ensure adequate urine flow during that period (with good hydration). Other nephrotoxic drugs, pre-existing renal disease and dehydration increase the risk of further renal impairment. Antidote: No known antidote, but haemodialysis can remove aciclovir from the circulation.

Adalimumab

40 mg solution in pre-filled pen or syringe

Adalimumab should be used under specialist supervision only.

- Adalimumab is a cytokine modulator.
- Adalimumab is licensed for use in the treatment of disease states where raised TNF levels are seen: active rheumatoid arthritis, ankylosing spondylitis, psoriatic arthritis, plaque psoriasis and Crohn's disease.
- Adalimumab has been assessed by NICE and in the UK should be used in accordance with the appropriate guidance.

Pre-treatment checks

- Screen for tuberculosis (TB): do not give in active TB or other severe infections.
- Do not use in moderate to severe heart failure.
- · Caution in hepatitis B virus: reactivation of hepatitis B has occurred in patients who are carriers.
- Caution should be exercised with demyelinating CNS disorders, as there is a risk of exacerbating symptoms.

Biochemical and other tests

ESR and CRP FBC LFTs Skin assessment (if being used for psoriasis) Tender joint count, swollen joint count (if being used for psoriatic or rheumatoid arthritis) U&Es

Dose

Rheumatoid arthritis: 40 mg by SC injection every 2 weeks in combination with methotrexate. If methotrexate is inappropriate or not tolerated, adalimumab dose may be increased to 40 mg every week.

Psoriatic arthritis and ankylosing spondylitis: 40 mg every 2 weeks.

Crohn's disease: initially 80 mg by SC injection, then 40 mg 2 weeks after initial dose. Accelerated regimen: initially 40 mg by SC injection for four doses over 1–2 days, then 80 mg 2 weeks after initial dose; maintenance, 40 mg every 2 weeks, increased if necessary to 40 mg every week. To induce remission, adalimumab is usually given in combination with a corticosteroid, but it may be given as monotherapy if a corticosteroid is inappropriate or not tolerated.

Psoriasis: 80 mg by SC injection initially, then 40 mg every 2 weeks commencing 1 week after initial dose.

This drug has not been studied in patients with renal or hepatic impairment; therefore no dose recommendations can be made.

Subcutaneous injection

Preparation and administration

- 1. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration before administration and discard if present.
- Give by SC injection into the thigh or abdomen. Avoid areas that are reddened, bruised or hard. If using the abdomen, give at least 5 cm from the umbilicus. Rotate injection sites for subsequent injections, ensuring they are at least 3 cm from a previous site.

14 | Adalimumab

Technical information			
Incompatible with	Not relevant		
Compatible with	Not relevant		
рН	Not relevant		
Sodium content	Negligible		
Storage	Store at 2-8°C in original packaging. Do not freeze.		

Monitoring

Measure	Frequency	Rationale
Clinical improvement	Periodically	• Discontinue treatment if there is no clinical response after 12 weeks for all licensed indications except psoriasis, where the treatment may continue for 16 weeks.
Infections	During and after treatment	 Serious infections, including tuberculosis, may occur. Adalimumab may take up to 5 months to be eliminated from the body; therefore monitoring should be continued during this period.
Injection sites	Post injection	 In controlled trials 15% of patients developed injection site reactions such as erythema, itching, haemorrhage, pain or swelling.
FBC, LFTs, U&Es, ESR and CRP	3 months after initiation and then every 6 months or in accordance with local policy	 Can affect liver function. May cause ↓haemoglobin. The other measures are used to assess therapeutic benefit or disease progression.

Additional information

Common and serious undesirable effects	Injection/infusion-related: Local: injection-site reactions, i.e. erythema, itching, pain, swelling. Other: Cough, headache, diarrhoea, abdominal pain, stomatitis, mouth ulcer, nausea, rash, pruritus, musculoskeletal pain, respiratory infections, fever, fatigue, ↑Alk Phos, ↑pulse.
Pharmacokinetics	Mean terminal half-life is about 2 weeks; it may take up to 5 months for adalimumab to be eliminated from the body.
Significant interactions	 The following may <i>î</i> adalimumab levels or effect (or <i>î</i>side-effects): abatacept (<i>î</i>risk of infections), anakinra (<i>î</i>risk of infections), live vaccines (avoid combination).
Action in case of overdose	No dose-limiting toxicity was observed during clinical trials.

(continued)

Additional information (continued)			
Counselling	Rep afte gra Pati Pati	Report signs or symptoms of infection, especially tuberculosis infection during or after treatment with adalimumab, e.g. persistent cough, wasting/weight loss, low- grade fever. Patients should be given a special alert card. Patients may receive concurrent vaccinations, except for live vaccines.	
Risk rating: GREEN	I	Score = 1 Lower-risk product: Risk-reduction strategies should be considered.	

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Bibliography

SPC Humira (accessed 21 October 2008).

Adenosine

3 mg/mL solution in 2-mL and 10-mL vials

- Adenosine is an endogenous nucleoside that is present in all cells of the body and is involved in many biological processes. It acts as an antiarrhythmic by stimulating adenosine A1-receptors and slowing conduction through the AV node.
- It is used to restore sinus rhythm in the treatment of paroxysmal SVT, including that associated with the Wolff–Parkinson–White syndrome. It is also used for the differential diagnosis of SVTs and in myocardial imaging.

Pre-treatment checks

- Contraindicated in patients with second- or third-degree AV block (except in patients with a functioning artificial pacemaker); sick sinus syndrome (except in patients with a functioning artificial pacemaker); asthma.
- Caution in atrial fibrillation or flutter with accessory pathway (conduction down anomalous pathway may increase).
- Caution in heart transplant, prolonged QT interval or obstructive pulmonary disease.

Biochemical and other tests

Bodyweight in certain indications

Dose

Reversion to sinus rhythm in paroxysmal SVT:

Initial dose: 6 mg by rapid IV injection (3 mg in patients with heart transplant as very sensitive to
effects of adenosine). If it is essential to co-administer with dipyridamole, the initial dose should be
reduced to 0.5–1 mg.

16 | Adenosine

- Second dose: 12 mg by rapid IV injection, if the first dose is not effective within 1–2 minutes (6 mg in patients with heart transplant).
- Third dose: 12 mg by rapid IV injection if the second dose is not effective within 1-2 minutes.

Aid to diagnosis of broad or narrow complex SVT: the above ascending dosage schedule is given until sufficient diagnostic information has been obtained.

In conjunction with radionuclide myocardial perfusion imaging: 140 micrograms/kg/minute by IV infusion for 6 minutes (see Table A2). The radionuclide is injected after 3 minutes of infusion.

Intravenous injection

Preparation and administration

For administration via a central or large peripheral vein only.

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration before administration and discard if present.
- 3. Give by rapid IV injection over 2 seconds into a central or large peripheral vein at a site as close to the cannulation site as possible.
- 4. Follow by a rapid flush of 20 mL NaCl 0.9%.
- 5. Discard any unused solution immediately.

Table A2	Dose of adenosine 3 mg/mL for myocardial perfusion scanning in m	_/
minute		

Bodyweight (kg)	Infusion rate (mL/ minute)	Bodyweight (kg)	Infusion rate (mL/ minute)
45-49	2.1	75-79	3.5
50-54	2.3	80-84	3.8
55-59	2.6	85-89	4.0
60-64	2.8	90-94	4.2
65-69	3.0	95-99	4.4
70-74	3.3	100-104	4.7

Intravenous infusion via a syringe pump (myocardial perfusion imaging)

Preparation and administration

For administration via a large peripheral vein only

- 1. Withdraw the required injection volume into a suitable syringe.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 6 minutes into a large peripheral vein at the rate specified above. Separate venous infusion sites for adenosine and radionuclide administration are recommended to avoid an adenosine bolus effect.

Adenosine | 17

Technical information				
Incompatible with		No information		
Compatible with		Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, Hartmann's Y-site: Abciximab		
рН		4.5-7.5		
Sodium content		Negligible		
Storage		Store below 30 Discard unused	D°C but do not refrigerate (risk of crystal formation). d injection solution immediately.	
Monitoring				
Measure	Fr	equency	Rationale	
ECG	Du	uring dministration	 Possibility of transient cardiac arrhythmias arising during conversion of the SVT to normal sinus rhythm. Increments should not be given if high-level AV block develops at any particular dose. 	
Heart rate and blood pressure	Ev du ac	very minute uring IV dministration	 To avoid an adenosine bolus effect BP should be measured in the arm opposite to the infusion. May rarely produce significant ↓BP and reflex ↑pulse. 	
Additional in	for	mation		
Common and serior undesirable effects	US	<i>Immediate</i> : Include transient facial flush, chest pain, dyspnoea, bronchospasm, choking sensation, nausea, light-headedness; severe ⊥pulse reported (requiring temporary pacing); ECG may show transient rhythm disturbances.		
Pharmacokinetics		Elimination half-life is <10 seconds.		
Significant interactions		 Dipyridamole may ↑adenosine effect (or ↑side-effects): initial dose should be reduced to 0.5-1 mg. The following may ↓adenosine effect: aminophylline, theophylline and other xanthines such as caffeine are known potent inhibitors of adenosine. 		
Action in case of overdose		No cases of overdosage have been reported.		
Counselling		Advise of the potential for the above undesirable effects and advise avoidance of methylxanthines, e.g. coffee, tea.		
		_		

Risk rating: AMBER	$\label{eq:score} \begin{array}{l} \mbox{Score} = 4 \\ \mbox{Moderate-risk product: Risk-reduction strategies are recommended.} \end{array}$	

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.
Bibliography

SPC Adenocor (accessed 25 February 2010). SPC Adenoscan (accessed 25 February 2010).

Adrenaline (epinephrine)

1 mg/mL (1 in 1000) solution in ampoules and pre-filled syringes 1 mg/mL (1 in 1000) solution in 0.15-mL and 0.3-mL auto-injector 0.1 mg/mL (1 in 10000) solution in 3-mL and 10-mL pre-filled syringes

- Adrenaline is an endogenous substance that is produced in the adrenal medulla and has directacting sympathomimetic activity.
- It is used in the emergency treatment of acute allergy, anaphylactic shock and for cardiac resuscitation.
- The IM route is preferred in shock and allergy because absorption from this route is more reliable than from SC injection.
- The IV route is used for advanced cardiac life support and where there is doubt regarding circulatory adequacy and absorption from IM dosing. The IV route is also used in critical care for low cardiac output states.

Pre-treatment checks

- Contraindications are relative as the drug is used in life-threatening emergencies.
- Outside of emergency situations, the following contraindications should be considered: hyperthyroidism, hypertension, ischaemic heart disease, arrhythmias, diabetes mellitus and closedangle glaucoma.
- · Do not inject into fingers, toes, ears, nose or genitalia owing to the risk of ischaemic tissue necrosis.

Biochemical and other tests (not all are necessary in an emergency situation)

None practical in emergency scenarios

Dose

Selection of the correct strength of adrenaline injection is crucial.

Acute anaphylaxis in adults by IM route: 500 micrograms (0.5 mL of the 1 in 1000 injection) by IM injection. The dose may be repeated if necessary at 5- to 15-minute intervals. Alternatively, 300 micrograms (0.3 mL of the 1 in 1000 injection) may be given using an auto-injector in patients with history or at risk of anaphylaxis.

Acute anaphylaxis in adults by IV route (use with extreme care only if the IM route is clearly ineffective): 50 micrograms (0.5 mL of the 1 in 10 000 injection) over 2–3 minutes. Repeat according to response. Consider infusion if multiple doses are required.

Advanced cardiac life support: refer to local resuscitation guidelines for use in CPR via IV or intraosseous routes.

Intraosseous route: doses are the same as those used IV.

Endotracheal route (only if circulatory access cannot be obtained): 2–3 mg diluted to 20–30 mL with NaCl 0.9% via *endotracheal tube*, repeated as necessary. Intracardiac injection is no longer recommended.

Low cardiac output states: 0.01–0.3 microgram/kg/minute by IV infusion. Adjust dose according to clinical response: heart rate, BP, cardiac output, presence of ectopic beats and urine output.

Intramuscular injection

Preparation and administration

Selection of the correct strength of adrenaline injection is crucial.

- 1. Withdraw the required dose or, if using an auto-injector device, follow the manufacturer's instructions for preparation of the dose.
- 2. Give by IM injection into the mid-point of the anterolateral aspect of the thigh through clothing if necessary (avoid injecting into the buttock because of the risk of tissue necrosis).

Intravenous injection in acute anaphylaxis (only if the IM route is ineffective)

Preparation and administration

For administration via a central line if possible. If a peripheral vein is used, flush with NaCl 0.9% immediately after injection.

Selection of the correct strength of adrenaline injection is crucial.

- 1. Withdraw the required dose. Dilute to 5 mL with NaCl 0.9% to facilitate slow administration.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV injection over 2–3 minutes into a central vein if possible (if a peripheral vein is used. flush immediately afterwards with 20 mL NaCl 0.9%).

Continuous intravenous infusion via syringe pump

Preparation of a 80 microgram/mL solution (various regimens may be used)

For administration via a central line. Selection of the correct strength of adrenaline injection is crucial.

- 1. Withdraw 4 mg and make up to 50 mL in a syringe pump with a compatible infusion solution.
- 2. Cap the syringe and mix well to give a solution containing 80 micrograms/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

Administration

Give by IV infusion into a central vein using a syringe pump.

Technical information		
Incompatible with	Sodium bicarbonate. Aminophylline, ampicillin, pantoprazole, micafungin.	
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, Gluc-NaCl, Hartmann's, Ringer's (including added KCl) Y-site: Amikacin, atracurium, calcium chloride, calcium gluconate, cisatracurium, clonidine, dobutamine, dopamine, fentanyl, furosemide, glyceryl trinitrate, hydrocortisone sodium succinate, labetalol, midazolam, milrinone, noradrenaline, propofol, ranitidine, remifentanil, tigecycline, tirofiban, vecuronium, verapamil	

20 | Adrenaline

Technical information (continued)		
рН	2.2-5	
Sodium content	Negligible	
Excipients	Contains sulfites (may cause hypersensitivity reactions).	
Storage	Store below 25°C in original packaging. Discoloured solutions or solutions containing a precipitate should not be used.	
Stability after preparation	From a microbiological point of view should be used immediately; however, prepared infusions may be stored at 2-8 $^\circ$ C and infused (at room temperature) within 24 hours.	

Monitoring

Measure	Frequency	Rationale
Respiratory function and airway patency	Continuously	• Response to therapy - anaphylaxis.
Blood pressure		• ↑BP desired response to therapy.
Heart rate/ECG		 ↑Pulse desired response to therapy. Arrhythmias may occur.
Cardiac and urine output	Hourly	Response to therapy.
Blood glucose	12 hourly	• Hyperglycaemia may occur.

Additional information

Common and serious undesirable effects	Injection/infusion-related: Local: Tissue necrosis at injection site. Other: Hyperglycaemia, ⊥K, palpitations, ↑pulse, arrhythmias, ↑BP, cold extremities, tremor, anxiety, headache, cerebral haemorrhage, dyspnoea, angle-closure glaucoma, nausea
Pharmacokinetics	Serum half-life 2-3 minutes. After SC or IM injection effects may be delayed due to vasoconstriction.
Significant interactions	 The following may <i>iddrenaline levels</i> or effect (or <i>iside-effects</i>): dopexamine, MAOIs (risk of hypertensive crisis), moclobemide (risk of hypertensive crisis), rasagiline (avoid combination). Beta-blockers may <i>iddrenaline levels</i> or effect. Adrenaline may <i>ilevels</i> or effect of the following drugs (or <i>iside-effects</i>): anaesthetics, general-volatile (<i>irisk</i> of arrhythmias); antidepressants-tricyclic (risk of arrhythmias and <i>iBP</i>); beta-blockers (risk of severe <i>iBP</i> and <i>ipulse</i>); tolazoline (avoid combination).
Action in case of overdose	<i>Symptoms to watch for:</i> Effects are short lived and typically require supportive measures only. Stop administration and give supportive therapy as appropriate.
Counselling	Correct technique for use of auto-injector.

Risk rating: GREEN	Score = 1 Lower-risk product: Risk-reduction strategies should be considered.	
This assessment does not cover IV infusion technique.

SPC Epinephrine (Adrenaline) Injection 1:10000, International Medication Systems (UK) Ltd (accessed 30 April 2009).

SPC EpiPen Jr. Auto-Injector 0.15 mg (accessed 30 April 2009).

Alfacalcidol (1α-hydroxycholecalciferol)

1 microgram/0.5 mL and 2 micrograms/mL solution in ampoules

- The term vitamin D is used for a range of closely related sterol compounds including alfacalcidol, calcitriol, colecalciferol and ergocalciferol. Vitamin D compounds possess the property of preventing or curing rickets.
- Alfacalcidol injection is indicated in the treatment of renal osteodystrophy; hyperparathyroidism (with bone disease); hypoparathyroidism; nutritional and malabsorptive rickets and osteomalacia; pseudo-deficiency (vitamin D-dependent) rickets and osteomalacia; hypophosphataemic vitamin D-resistant rickets and osteomalacia.

Pre-treatment checks

- Do not give to patients with hypercalcaemia, including hypercalcaemia of malignancy.
- In patients with renal bone disease, relatively high initial plasma Ca levels may indicate autonomous hyperparathyroidism, which is often unresponsive to alfacalcidol.

Biochemical and other tests

Electrolytes: serum Ca, PO₄ Liver function: Alk Phos Renal function: U, Cr, CrCl (or eGFR)

Dose

Initial adult dose: 1 microgram/day. Adjust dose according to biochemical response taking care to avoid \uparrow Ca. Maintenance doses are generally in the range of 250 nanograms to 1 microgram/day. **Initial dosage in elderly patients:** 500 nanograms/day.

22 | Alfacalcidol

Patients undergoing haemodialysis: the initial dosage for adults is 1 microgram/dialysis. The maximum recommended dose is 6 micrograms/dialysis and not more than 12 micrograms/ week. The injection is given into the return line from the haemodialysis machine at the end of each dialysis.

Intravenous injection

Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IV injection over approximately 30 seconds.

Technical information		
Incompatible with	No information	
Compatible with	No information	
рН	No information	
Sodium content	Negligible	
Excipients	Contains ethanol (may interact with metronidazole, possible religious objections). Contains propylene glycol (adverse effects seen in ↓renal function, may interact with disulfiram and metronidazole).	
Storage	Store at 2-8°C in original packaging.	

Monitoring

Measure	Frequency	Rationale
Serum Ca and PO_4	Initially weekly until dose and plasma Ca and PO_4 are stable, then monthly; also whenever nausea or vomiting occurs.	 ↑Ca and ↑PO₄ can occur during treatment with pharmacological doses of compounds having vitamin D activity. Plasma PO₄ concentrations should be controlled to reduce the risk of ectopic calcification.
Alk Phos	Monthly	 A fall in serum Alk Phos level often precedes the appearance of ↑Ca.
Renal function	Periodically	• Increased risk of ↑Ca in renal impairment.
Ophthalmological examination		• To check for ectopic calcification.
Signs/symptoms of toxicity		 Typically these are: persistent constipation or diarrhoea, constant headache, loss of appetite, mental changes.

Additional information		
Common and serious undesirable effects	↑Ca (persistent constipation or diarrhoea, constant headache, vertigo, loss of appetite, polyuria, thirst, sweating), rash. Rarely nephrocalcinosis, pruritus, urticaria.	
Pharmacokinetics	Formation of 1,25 dihydroxycholecalciferol occurs within 1 hour after IV injection and peak concentrations are reached in 2-5 hours. Elimination half-life of the formed 1,25 dihydroxycholecalciferol is 14-30 hours.	
Significant interactions	Injectable preparation contains ethanol and propylene glycol: may interact with disulfiram and metronidazole.	
Action in case of overdose	Symptoms to watch for: \uparrow Ca. Stop treatment until plasma Ca levels return to normal (about 1 week). Restart treatment at half the previous dose if appropriate.	
Counselling	Advise to report symptoms of †Ca: persistent constipation or diarrhoea, constant headache, vertigo, loss of appetite, polyuria, thirst, sweating. Advise of the need for further blood tests.	

Risk rating: GREEN	Score = 1 Lower-risk product: Risk-reduction strategies should be considered.

Bibliography

SPC One-Alpha injection (accessed 25 January 2009).

Alteplase (recombinant tissue-type plasminogen activator, rt-PA, TPA)

10-mg, 20-mg and 50-mg dry powder vials with solvent (WFI)

- Alteplase is a form of endogenous tissue plasminogen activator produced by recombinant DNA technology. It has thrombolytic activity.
- It is licensed for the dissolution of clots in MI, acute massive PE with haemodynamic instability and acute ischaemic stroke.
- · It has also been used (unlicensed) to dissolve clots in a variety of other circumstances.
- Each 1 mg of alteplase provides 580 000 units of human recombinant tissue plasminogen activator activity.

Pre-treatment checks

- Contraindicated in recent haemorrhage, trauma, or surgery (including dental extraction); coagulation defects; bleeding diatheses; aortic dissection; aneurysm; coma; history of cerebrovascular disease, especially recent events or with any residual disability; recent symptoms of possible peptic ulceration; heavy vaginal bleeding; severe *1BP*; active pulmonary disease with cavitation; acute pancreatitis; pericarditis; bacterial endocarditis; severe liver disease; and oesophageal varices.
- Caution in acute stroke; monitor for intracranial haemorrhage; monitor BP (antihypertensive recommended if systolic >180 mmHg or diastolic >105 mmHg).
- Use with caution if there is a risk of bleeding including that from venepuncture or invasive procedures.
- Caution in external chest compression, pregnancy, elderly (contraindicated if >80 years), \pprime BP, conditions in which thrombolysis might give rise to embolic complications such as enlarged left atrium with atrial fibrillation (risk of dissolution of clot and subsequent embolisation), and recent or concurrent use of drugs that \prisk of bleeding.
- Administration of aspirin or IV heparin should be avoided in the first 24 hours after treatment but if heparin is required for other indications the dose should not exceed 10 000 units per day SC.

Additional contraindications in acute myocardial infarction/acute pulmonary embolism: known history of ischaemic stroke or TIA in the preceding 6 months, except current acute ischaemic stroke within 3 hours.

Additional contraindications in acute ischaemic stroke: convulsion accompanying stroke, severe stroke, history of stroke in patients with diabetes, stroke in last 3 months, hypoglycaemia, hyperglycaemia.

Biochemical and other tests (not all are necessary in an emergency situation)

Blood glucose – do not give if <2.8 or >22 mmol/L. Blood pressure and pulse – do not give if systolic BP >185 or diastolic BP >110 mmHg, or if aggressive management (IV pharmacotherapy) is necessary to reduce BP to these limits. Bodyweight (in certain indications). FBC – do not give if platelets <100 000/mm³. LFTs – do not give in severe disease.

Dose

Myocardial infarction within 6 hours of symptom onset (patients \geq **65 kg):** 15 mg by IV injection, then 50 mg by IV infusion over 30 minutes, then 35 mg by IV infusion over 60 minutes (total dose 100 mg over 90 minutes).

Myocardial infarction within 6 hours of symptom onset (patients <**65 kg):** 15 mg by IV injection, then 0.75 mg/kg by IV infusion over 30 minutes, then 0.5 mg/kg by IV infusion over 60 minutes (maximum total dose 100 mg over 90 minutes).

Myocardial infarction between 6 and 12 hours of symptom onset (patients \geq 65 kg): 10 mg by IV injection, then 50 mg by IV infusion over 60 minutes, then 40 mg by IV infusion over 2 hours (total dose 100 mg over 3 hours).

Myocardial infarction between 6 and 12 hours of symptom onset (patients <**65 kg):** as above up to a total dose of 1.5 mg/kg over 3 hours.

Pulmonary embolism (patients \geq **65 kg):** 10 mg by IV injection followed by 90 mg by IV infusion over 2 hours.

Pulmonary embolism (patients <**65 kg):** as above up to a total dose of 1.5 mg/kg (maximum total dose 100 mg).

Acute ischaemic stroke within 3 hours of symptom onset: calculate the total dose, i.e. 900 micrograms/kg (maximum total dose 90 mg). Give 10% of the total dose by IV injection and the remainder by IV infusion over 60 minutes.

Central venous catheter occlusion (unlicensed): a 1 mg/mL solution has been used instilled into the catheter. A typical dose is 2 mg, repeated after 2 hours if necessary (maximum total dose 4 mg).

Intracardiac thrombosis of prosthetic heart valves (unlicensed): 100 mg has been given by IV infusion over 2 hours.

Peripheral arterial thromboembolism (unlicensed): doses of 0.2–1 mg/hour by intra-arterial infusion have been commonly used.

Removal of distal clots during a surgical procedure (unlicensed): alteplase has been given intra-arterially as three doses of 5 mg at 10-minute intervals.

Intravenous injection

Preparation and administration

Alteplase is incompatible with Gluc solutions.

- 1. Calculate the volume of solvent (WFI) to produce a solution containing 1 or 2 mg/mL.
- Using a syringe and wide-bore needle or the manufacturer's transfer device (only for 1 mg/mL solutions), direct the stream of WFI directly into the lyophilised cake.
- 3. Gently swirl the vial (do not shake) to dissolve the drug. Allow to stand if necessary to dissipate bubbles.
- 4. Withdraw the required dose.
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 6. Give by IV injection over 1-2 minutes.

Intravenous infusion

Preparation and administration

Alteplase is incompatible with Gluc solutions.

- 1. Calculate the volume of solvent (WFI) to produce a solution containing 1 mg/mL.
- Using a syringe and wide-bore needle or the manufacturer's transfer device (if available), direct the stream of WFI directly into the lyophilised cake.
- 3. Gently swirl the vial (do not shake) to dissolve the drug. Allow to stand if necessary to dissipate bubbles.
- 4. Withdraw the required dose (bearing in mind that infusion solutions are only stable for up to 8 hours at room temperature).
- 5. The solution may be infused at the 1 mg/mL concentration as prepared.
- Alternatively dilute to 5 times the volume with NaCl 0.9% to give a solution containing 0.2 mg/mL.
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 8. Give by IV infusion via a volumetric infusion device at a rate appropriate to the indication. Prepare a fresh infusion solution every 8 hours if required.

Technical information		
Incompatible with	Alteplase is incompatible with Gluc solutions. Bivalirudin, dobutamine, dopamine, glyceryl trinitrate, heparin sodium.	
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9% Y-site: Lidocaine, metoprolol	
рН	6.8-7.8	

26 | Alteplase

Technical information (continued)			
Sodium content	Negligible		
Storage	Store below 25°C in original packaging. Protect from light.		
Displacement value	Negligible		
Stability after preparation	From a microbiological point of view, should be used immediately; however: Reconstituted vials and prepared infusions may be stored at 2-8°C and given (at room temperature) within 24 hours. Prepared infusions are stable at room temperature for up to 8 hours.		
Monitoring			
Measure	Frequency	Rationale	
In treatment of myo	cardial infarction		
Heart rate	Continuously	• ↓Pulse may result from reperfusion.	
ECG		Arrhythmias may result from reperfusion.	
Blood pressure		 LBP may occur. Raise legs and slow or stop infusion temporarily. 	
In treatment of ischaemic stroke			
Blood pressure and neurological observations	Continuously	 STOP infusion if: Marked ↓BP. Neurological deterioration, i.e. Conscious level (2 points GCS eye/motor score) NIHSS >4 points. ↑BP >185/110 mmHg if sustained or associated with neurological deterioration. 	
Additional infor	mation		
Common and serious undesirable effects	Immediate: Anaphylaxis and other hypersensitivity reactions have been reported rarely. Injection/infusion-related: Local: Haemorrhage at injection site. Other: Bleeding, LBP, for Lpulse, coronary artery reperfusion events, e.g. rhythm disorders, nausea, vomiting, headache, muscle pain, fever.		
Pharmacokinetics	Elimination half-life	is around 40 minutes.	
Significant interactions	 The following may <i>\risk</i> of haemorrhage with alteplase: anticoagulants, heparins, antiplatelet agents, e.g. aspirin, clopidogrel, dipyridamole, GP IIb/IIIa inhibitors. 		
Action in case of overdose	Symptoms to watch Antidote: No specif as appropriate inclu if necessary.	n for: Severe bleeding. fic antidote. Stop administration and give supportive therapy uding fresh frozen plasma, fresh blood and tranexamic acid	
Counselling	Report bleeding events.		

Bibliography

SPC Actilyse (accessed 31 March 2010).

Amikacin

100 mg/2 mL, 500 mg/2 mL solution in vials

- Amikacin sulfate is a semi-synthetic aminoglycoside antibiotic derived from kanamycin A.
- It is used similarly to gentamicin in the treatment of severe Gram-negative and other infections.
- Doses are expressed in terms of the base: Amikacin $1 g \cong 1.3 g$ amikacin sulfate.

Pre-treatment checks

- · Do not use in myasthenia gravis.
- Use with caution in patients with eighth cranial nerve damage.
- · Ensure patient is well hydrated prior to during treatment.

Biochemical and other tests

Bodyweight Renal function: U, Cr, CrCl (or eGFR)

Dose

Standard dose: 7.5 mg/kg every 12 hours, increased to 7.5 mg/kg every 8 hours in severe infections. **Life-threatening infections and/or those caused by** *Pseudomonas:* up to 500 mg every 8 hours and for no more than 10 days (maximum total treatment dose should not exceed 15 g). **Dose in renal impairment**: adjusted according to creatinine clearance.¹

• CrCl > 20–50 mL/minute: 5–6 mg/kg every 12 hours

- CrCl 10–20 mL/minute: 3–4 mg/kg every 12 hours
- CrCl <10 mL/minute: 2 mg/kg every 24-48 hours

Intramuscular injection (preferred route, unless not feasible or in lifethreatening infections)

Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by deep IM injection into the upper outer quadrant of the buttocks.

Intravenous injection

Preparation and administration

If used in combination with a penicillin or cephalosporin, administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Withdraw the required dose.
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 2-3 minutes.

Intermittent intravenous infusion

Preparation and administration

If used in combination with a penicillin or cephalosporin, administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually 100 mL NaCl 0.9%).
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 30 minutes.

Technical inform	ation
Incompatible with	Potassium chloride. Aminophylline, amphotericin B, ampicillin, benzylpenicillin, cefotaxime, ceftazidime, ceftriaxone, cefuroxime, gentamicin, heparin sodium, Pabrinex, pantoprazole, phenytoin sodium, propofol, tobramycin.
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, Hartmann's Y-site: Aciclovir, adrenaline (epinephrine), calcium gluconate, chloramphenicol sodium succinate, ciprofloxacin, cisatracurium, clindamycin, dexamethasone, esmolol, fluconazole, furosemide, granisetron, hydrocortisone sodium succinate, labetalol, magnesium sulfate, metronidazole, midazolam, noradrenaline (norepinephrine), ondansetron, phytomenadione (mixed micelles), ranitidine, remifentanil, tigecycline, sodium bicarbonate, vancomycin, verapamil
рН	3.5-5.5
Sodium content	Negligible
Excipients	Contains sulfites (may cause hypersensitivity reactions).
Storage	Store below 25°C in original packaging.
Stability after reconstitution	From a microbiological point of view should be used immediately; however, prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours.

Monitoring

Measure	Frequency	Rationale
Vestibular and auditory function	Daily	 Ototoxicity is a potential effect of over exposure to amikacin. Check there is no deterioration of balance or hearing - if there is this may be indicative of toxic levels.
Signs of nephrotoxicity		 If signs of renal irritation occur, e.g. albumin, casts, red or white blood cells in urine: increase hydration and consider dosage reduction. If azotaemia or a progressive decrease in urine output occurs: stop therapy.
Amikacin serum concentration	See right-hand column for details of first measurement. Twice weekly in normal renal function; more frequently if renal function is impaired	 For meaningful interpretation of results the laboratory request form must state: the time the previous dose was given the time the blood sample was taken The first measurements should be made around the third dose. A trough level is taken just before this dose and should be <10 mg/L. A peak level is taken 1 hour after the dose has been given and should not exceed 30 mg/L (35 mg/L is stated in USA).
Renal function	Periodically	 If CrCl (or eGFR) changes a dose adjustment may be necessary.

Additional information

Common and serious undesirable effects	Common vestibular and auditory damage, nephrotoxicity.
Pharmacokinetics	Elimination half-life is 2-3 hours in normal renal function.
Significant interactions	 Amikacin may †risk of nephrotoxicity with the following drugs: ciclosporin, platinum compounds, tacrolimus. Amikacin may 1 levels or effect of the following drugs (or 1 side-effects): diuretics-loop (1 risk of ototoxicity), muscle relaxants non-depolarising, suxamethonium. Amikacin may 1 levels or effect of the following drugs: neostigmine, pyridostigmine.
Action in case of overdose	Antidote: None, but haemodialysis may be effective. Stop administration and give supportive therapy as appropriate.

Risk rating: AMBER	$\label{eq:Score} \begin{array}{l} Score = 3 \\ Moderate-risk \ product \text{: Risk-reduction strategies are recommended.} \end{array}$

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Aminophylline

25 mg/mL solution in 10-mL ampoules; 250 mg/mL solution in 2-mL ampoules

- Aminophylline is a soluble complex of theophylline and rapidly liberates theophylline after injection or infusion. It relaxes bronchial smooth muscle, relieves bronchospasm, and has a stimulant effect on respiration. It also stimulates the myocardium and CNS, peripheral resistance and venous pressure, and causes diuresis.
- Aminophylline IV may be used to treat acute bronchospasm including acute severe asthma and acute exacerbation of COPD.
- Aminophylline has a low therapeutic index, i.e. there is a narrow effective range outside which a
 dose is toxic or sub-therapeutic. Serum levels should be monitored regularly, particularly during
 initiation of therapy. The pharmacokinetics of theophylline are affected by several factors including age, smoking, disease, diet, and drug interactions.
- If therapeutic doses of aminophylline and/or theophylline are administered simultaneously by more than one route or in more than one preparation, the hazard of serious toxicity is increased.
- In the UK doses are usually expressed in terms of the base: Aminophylline $1 \text{ mg} \equiv 1.09 \text{ mg}$ aminophylline hydrate.
- In the USA aminophylline is required to be labelled in terms of anhydrous theophylline content: Aminophylline 600 micrograms ≅ 500 micrograms theophylline.

Pre-treatment checks

- Do not use in patients hypersensitive to ethylenediamine or those allergic to xanthine derivatives, e.g. theophylline, caffeine.
- Do not use in acute porphyria.
- In patients currently receiving theophylline preparations, the loading dose should be deferred until a serum theophylline concentration can be attained or the clinician must carefully select a dose based on the potential benefits and risks. Knowledge of the time, route of administration and dosage form of the patient's last theophylline dose may inform this decision.
- Caution in patients undergoing influenza immunisation or who have active influenza infection or acute febrile illness – theophylline clearance may be reduced.
- Caution in patients with cardiac failure, COPD, renal or hepatic dysfunction and in chronic alcoholism – theophylline clearance may be reduced.
- Use with caution in patients with peptic ulcer, hyperthyroidism, glaucoma, diabetes mellitus, severe hypoxaemia, ↑BP, compromised cardiac or circulatory function and epilepsy, as these conditions may be exacerbated.
- Smoking status (tobacco or marijuana) should be determined: theophylline clearance may be increased in smokers and in those regularly exposed to tobacco smoke.

Biochemical and other tests (not all are necessary in an emergency situation)

Electrolytes: serum K Ideal bodyweight (and therefore patient's height) LFTs

Plasma theophylline concentration for patients already taking therapy (especially if previous dose within the past 24 hours)

Dose

Severe acute asthma or acute exacerbation of COPD

A 250 mg/mL injection is available for IM use but this route causes intense local pain and is not recommended.

To avoid excessive dosing, doses should be calculated on the basis of ideal bodyweight (IBW) in obese patients.

Loading dose for patients not on oral theophylline/aminophylline: 250–500 mg (\cong 5 mg/kg IBW) by slow IV injection over at least 20 minutes with close monitoring. Follow immediately by a maintenance infusion (see below). Loading doses are based on the expectation that 0.5 mg/kg of theophylline will result in a 1 microgram/mL increase in serum theophylline concentration.

Loading dose for patients already on oral theophylline/aminophylline:

- Defer treatment until serum theophylline level is available. Adjust loading dose on the basis that each 600 microgram/kg IBW of aminophylline will increase plasma theophylline concentration by 1 mg/L. Follow immediately by a maintenance infusion (see below).
- Alternatively, if there are compelling reasons to proceed omit the loading dose and start the maintenance infusion (see below).

Maintenance dose by continuous IV infusion:

- Initial dose:
 - · Otherwise healthy non-smoking adults: 500 micrograms/kg IBW/hour
 - Elderly persons, in cor pulmonale, heart failure, or liver disease: 300 micrograms/kg IBW/hour
 - · Children 10-16 years of age and young adult smokers: 700-800 micrograms/kg IBW/hour
- Adjust dose according to plasma theophylline concentration see Monitoring in the table below.

Intravenous injection via a syringe pump

This method is used for the *loading* dose only – the infusion rate must be reduced after the initial 20-minute loading infusion.

Preparation of a 10 mg/mL solution (other strengths may be used according to local policies)

- 1. Withdraw 500 mg aminophylline (20 mL of 25 mg/mL solution) into a 50-mL syringe.
- 2. Make up to a final volume of 50 mL with Gluc 5% or NaCl 0.9%.
- 3. Cap the syringe and mix well to give a solution containing 10 mg/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

Administration

- Give by IV infusion using a syringe pump for 20 minutes only at the rate specified in the chart below. The rate should never exceed 25 mg/minute (150 mL/hour). If patients experience acute adverse effects while the loading dose is being infused, either stop the infusion for 5–10 minutes or give at a slower rate. Table A3 gives further guidance.
- 2. Discard any infusion remaining at the end of 20 minutes.

Fluid restriction: the maximum concentration that can be given is 25 mg/mL via a central line.

Ideal bodyweight (kg)	Dose (mg)	Volume of 10 mg/mL containing required dose (mL)	Loading dose infusion rate for 20 minutes only (mL/hour)
40	200	20	60
45	225	22.5	67.5
50	250	25	75
55	275	27.5	82.5

90	450	45	135

Table A3 Am	ninophylline	loading dos	e: rate of infusio	n using a	10 mg/mL solution
-------------	--------------	-------------	--------------------	-----------	-------------------

Continuous intravenous infusion (maintenance infusion)

Preparation of a 1 mg/mL solution (other strengths may be used according to local policies)

- 1. Remove 20 mL from a 500-mL bag of Gluc 5% or NaCl 0.9% and discard.
- 2. Withdraw 500 mg aminophylline (20 mL of 25 mg/mL solution) and add to the prepared infusion bag.
- 3. Mix well to give a solution containing 1 mg/mL.
- 4. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by IV infusion via a volumetric infusion device at the required rate (see Table A4).
- 6. Prepare a fresh infusion bag at least every 24 hours if required.

Fluid restriction: the maximum concentration that can be given is 25 g/mL via a central line.

ldeal bodyweight (kg)	300 micrograms/kg/hour (mL/hour)	500 micrograms/kg/hour (mL/hour)	800 micrograms/kg/hour (mL/hour)

 Table A4
 Aminophylline maintenance dose: rate of infusion using a 1 mg/mL solution

Technical inform	ation
Incompatible with	Should not be allowed to come into contact with metals. Amiodarone, ciprofloxacin, cisatracurium, clarithromycin, dobutamine, hydralazine, ondansetron.
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, Hartmann's (all with added KCl) Y-site: Aztreonam, ceftazidime, fluconazole, foscarnet, linezolid, meropenem, micafungin, piperacillin with tazobactam, ranitidine, remifentanil, vecuronium bromide
рН	8.6-10 (precipitation occurs at pH <8)
Sodium content	Nil
Excipients	Contains ethylenediamine (may cause hypersensitivity reactions).
Storage	Store below 25°C in original packaging. Protect from light. Do not freeze. Discard ampoule if contents discoloured.
Stability after preparation	Use prepared infusions immediately; change every 24 hours.

34 | Aminophylline

Monitoring			
Measure	Frequency	Rationale	
Plasma theophylline concentration	30 minutes after loading dose then 4-6 hours after the start of IV infusion until target concentration is achieved. Re-check 24 hours after dose adjustments.	 Target plasma-theophylline concentration for optimum response: 10-20 mg/L (55-110 micromol/L). Toxicity is most likely to occur when plasma concentration exceeds 20 micrograms/mL. There is marked inter-patient variation in the dosage required to achieve plasma levels of theophylline within the desired therapeutic range. If theophylline concentrations are <9.9 mg/L (<55 micromol/L): increase infusion rate by 25% if symptoms are <i>not</i> controlled and current dosage is tolerated. 10-14.9 mg/L (55-82 micromol/L): maintain infusion rate if symptoms are controlled and current dosage is tolerated. 15-19.9 mg/L (82.5-109 micromol/L): consider 10% decrease in infusion rate to provide greater margin of safety even if current dosage is tolerated. 20-24.9 mg/L (110-137 micromol/L): decrease infusion rate by 25% even if no adverse effects are present. 25-30 mg/L (137.5-165 micromol/L): stop infusion for 24 hours (in adults); re-check level before resuming. Decrease previous infusion rate by about 25%. >30 mg/L (>165 micromol/L): stop infusion and treat overdose as indicated. If therapy is resumed, decrease subsequent infusion rate by about 50% and recheck serum concentration after 24 hours. 	
ECG	During loading dose	Can cause cardiac arrhythmias.	
Serum K	Daily	 During regular therapy serum K levels must be monitored as ↓K may occur rapidly. This is particularly important during combination therapy with beta₂-agonists, corticosteroids or diuretics, or in the presence of hypoxia 	

Additional information

Common and serious undesirable effects	 Immediate: Anaphylaxis has been reported rarely. Injection/infusion-related: Too rapid administration: nausea, vomiting, arrhythmias, convulsions. Local: IM injections are very painful and should not be used. Other: <i>Pulse</i>, palpitations, nausea and other GI disturbances, headache, CNS stimulation, insomnia, arrhythmias.
Pharmacokinetics	Elimination half-life is about 8 hours in non-smoking adults; about 10-12 hours in elderly patients; about 32 hours in liver cirrhosis; about 3-5 hours in smokers.

Additional infor	Additional information (continued)		
Significant interactions	 The following may †theophylline levels or effect (or ↑side-effects): aciclovir, allopurinol, azithromycin, calcium-channel blockers, cimetidine, ciprofloxacin, clarithromycin, disulfiram, doxapram, erythromycin, fluconazole, fluvoxamine, halothane, influenza vaccine, interferon alfa, isoniazid, ketamine, ketoconazole, methotrexate, norfloxacin, oestrogens, pentoxifylline, propafenone, verapamil, zafirlukast. The following may †theophylline levels or effect: barbiturates, carbamazepine, phenytoin, primidone, rifampicin, ritonavir, St John's Wort, sulfinpyrazone, tobacco. Risk of ↓K with the following: acetazolamide, corticosteroids, diuretics, beta2-sympathomimetics. Theophylline may ↓levels or effect of the following drugs: adenosine, benzodiazepines, lithium, phenytoin, zafirlukast. 		
Action in case of overdose	Symptoms to watch for: †Pulse, nausea, vomiting, arrhythmias and seizures (may occur even without preceding symptoms of toxicity and often result in death). Profound LK may develop rapidly. Antidote: No known antidote. Consider charcoal haemoperfusion if plasma theophylline concentration >80 mg/L (acute) or >60 mg/L (chronic), or if >40 mg/L in elderly patients. Stop administration and give supportive therapy as appropriate.

SPC Aminophylline Injection, Hameln Pharmaceuticals Ltd (accessed 3 May 2010). SPC Aminophylline Injection BP 250 mg/10 mL, Goldshield plc (accessed 3 May 2010). SPC Aminophylline Injection BP 500 mg/2 mL, Goldshield plc (accessed 3 May 2010).

Amiodarone hydrochloride

50 mg/mL solution in 3-mL and 6-mL ampoules; 300 mg/10 mL solution in pre-filled syringes

- · Amiodarone hydrochloride is an antiarrhythmic with mainly class III properties.
- It is used in the control of ventricular and supraventricular arrhythmias, including arrhythmias associated with Wolff–Parkinson–White syndrome.

Pre-treatment checks

- Do not use in: ↓pulse, sinoatrial block, AV block or other severe conduction disorders (unless the patient has a pacemaker), severe ↓BP, and severe respiratory failure.
- Caution in heart failure.
- · Electrolyte disorders should be corrected before starting treatment.

Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure and pulse Bodyweight Chest X-ray ECG Electrolytes: serum Na, K, Ca, Mg LFTs (especially transaminases) TFTs

Dose

Arrhythmias:

- *Initial infusion:* 5 mg/kg by IV infusion over 20–120 minutes via a central venous catheter. The faster rate is used if rapid control of arrhythmias is required.
- *Subsequent infusion:* the initial dose may be followed by a subsequent infusion of approximately 15 mg/kg (up to a maximum of 1.2 g) over 24 hours. Adjust the rate according to clinical response.

As soon as an adequate response has been obtained oral therapy should be initiated concomitantly at the usual loading dose (e.g. 200 mg three times a day although this may be dependent on the duration of the IV therapy). IV therapy should then be phased out gradually according to clinical response.

Cardiopulmonary resuscitation: for ventricular fibrillation or pulseless tachycardia unresponsive to other interventions 150–300 mg or 5 mg/kg by IV injection. This should not be repeated for at least 15 minutes.

Intravenous infusion

Preparation and administration

Amiodarone is incompatible with NaCl 0.9%. Very irritant: repeated or continuous infusions should be given via a central line.

- 1. Withdraw the required dose and add to a suitable volume of Gluc 5% (use 250 mL for the initial infusion; use up to 500 mL for the subsequent infusion). Solutions containing less than 600 micrograms/mL in Gluc 5% are unstable.
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion via a volumetric infusion device at the rate specified above. Do not use a dropcounting infusion device because amiodarone affects drop size.

Intravenous injection (cardiopulmonary resuscitation only)

Preparation and administration

- The pre-filled syringe containing 300 mg/10 mL is ready for use. Expel any excess amiodarone. Alternatively withdraw 3–6 mL of 50 mg/mL solution from an ampoule, dilute to 10–20 mL with Gluc 5% and mix well.
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over a minimum of 3 minutes.

Technical inform	ation
Incompatible with	Amiodarone is incompatible with NaCl 0.9%. Avoid equipment containing the plasticiser diethylhexyl phthalate (DEHP). Aminophylline, bivalirudin, ceftazidime, digoxin, drotrecogin alfa (activated), furosemide, heparin sodium, imipenem with cilastatin, magnesium sulfate, micafungin, pantoprazole, piperacillin with tazobactam, sodium bicarbonate.
Compatible with	Flush: Gluc 5% Solutions: Gluc 5% (including added KCI) Y-site: Amikacin, benzylpenicillin, clindamycin, dobutamine, dopamine, glyceryl trinitrate, lidocaine, noradrenaline, tobramycin, vancomycin
рН	4
Sodium content	Nil
Excipients	Contains benzyl alcohol.
Storage	Store below 25°C in original packaging.
Stability after preparation	From a microbiological point of view should be used immediately; however, prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours. Solutions containing less than 600 micrograms/mL in Gluc 5% are unstable.

Monitoring

Measure	Frequency	Rationale
ECG during the loading dose for: heart rate, PR, QRS, and QT interval prolongation	Continuously	 Prolongation of the QT interval is indicative of a therapeutic antiarrhythmic effect. It has been suggested that initial loading doses be continued until significant prolongation of the QT interval (10-15%) is observed; further adjustments in dosage should be based upon maintaining this percentage of QT prolongation.
Blood pressure	Continuous during loading dose, periodically thereafter	• JBP and in rare instances cardiovascular collapse can occur.
TFTs	6 monthly if on long-term therapy	 Monitoring of T₄, T₃, and TSH levels is required as changes in thyroid function commonly occur requiring corrective action. Continue monitoring for several months following its discontinuation (this is particularly important in elderly patients).
LFTs and pulmonary function		 Long-term therapy with oral amiodarone requires periodic monitoring for thyroid, hepatic and pulmonary function.

Additional information		
Common and serious	 Immediate: Anaphylaxis has very rarely been reported. Also angioedema.	
undesirable effects	Injection/infusion-related: Too rapid administration: JBP, hot flushes, sweating, nausea. Local: discomfort and inflammation if given via a peripheral vein - central line advised. Injection site reactions are common (pain, erythema, oedema, necrosis, thrombophlebitis, phlebitis). Local tissue damage may occur following extravasation. Other: JPulse. Long-term use: pulmonary toxicity (pneumonitis, fibrosis, pleuritis), changes in thyroid function, corneal micro deposits, photosensitivity	
Pharmacokinetics	Elimination half-life: (single dose) 25 days; (chronic dose) 14-107 days (mean 52 days).	
Significant	 The following may ↑risk of ventricular arrhythmias with amiodarone (avoid combination):	
interactions	amisulpride, antidepressants-tricyclic, arsenic trioxide, artemether with lumefantrine, atomoxetine, benperidol, chloroquine, co-trimoxazole, disopyramide, droperidol, erythromycin-parenteral, fosamprenavir, haloperidol, hydroxychloroquine, ivabradine, levofloxacin, lithium, mefloquine, mizolastine, moxifloxacin, nelfinavir, pentamidine isetionate, phenothiazines, pimozide, quinine, ritonavir, sertindole, sotalol, sulfamethoxazole, sulfamethoxazole sulpiride, tolterodine, zuclopenthixol. The following may ↑amiodarone levels or effect (or ↑side-effects): atazanavir, beta-blockers (↑risk of ⊥pulse and AV block), diltiazem (↑risk of ⊥pulse and AV block). Amiodarone may ↑levels or effect of the following drugs (or ↑side-effects): acenocoumarol (monitor INR), dabigatran (↓dabigatran dose), digoxin (halve digoxin dose), flecainide (halve flecainide dose), phenindione (monitor INR), phenytoin (monitor levels), warfarin (monitor INR), simvastatin (↑risk of myopathy).	
Action in case of	Besides supportive measures, prolonged surveillance of the patient is required because of the long biological half of amiodarone.	
overdose	Severe ↓pulse; if necessary beta-agonists or glucagon may be given.	
Counselling	Phototoxicity awareness. Report respiratory symptoms after long-term therapy. Advise of the need for regular blood tests and for an annual ophthalmic examination.	

Risk rating: **RED**

Score = 6

High-risk product: Risk-reduction strategies are required to minimise these risks.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Bibliography

SPC Cordarone X intravenous (accessed 11 March 2010).

Amoxicillin (amoxycillin)

250-mg, 500-mg, 1-g dry powder vials

- Amoxicillin sodium is a penicillin.
- It is used for the treatment of infections caused by susceptible Gram-negative bacteria (e.g. *Haemophilus influenzae, Escherichia coli, Proteus mirabilis, Salmonella*) and also for susceptible Gram-positive bacteria (e.g. *Streptococcus pneumoniae*, enterococci, non-penicillinase-producing staphylococci, *Listeria*).
- · Amoxicillin must not be given intrathecally (potentially fatal encephalopathy has been reported).
- Doses are expressed in terms of the base: Amoxicillin 1 g ≡ 1.06 g amoxicillin sodium.

Pre-treatment checks

- · Do not give if there is known hypersensitivity to penicillins.
- Caution in erythematous rashes common in glandular fever, cytomegalovirus infection, and acute
 or chronic lymphocytic leukaemia.
- · Maintain adequate hydration with high doses.

Biochemical and other tests

FBC Renal function: U, Cr, CrCl (or eGFR)

Dose

Standard dose: 500 mg by IM or IV injection or IV infusion every 8 hours.

Severe infections: 1 g by IV injection or infusion every 6 hours.

Listerial meningitis (in combination with another antibiotic): 2 g by IV infusion every 4 hours for 10–14 days.

Endocarditis (in combination with another antibiotic if indicated): 2 g by IV infusion every 6 hours, increased to 2 g every 4 hours, e.g. in enterococcal endocarditis or in monotherapy.

Surgical prophylaxis: 1 g by IM or IV injection immediately before induction, followed by 500 mg 6 hours later. Check local policies.

Dose in renal impairment: adjusted according to creatinine clearance:¹

- CrCl >20-50 mL/minute: Dose as in normal renal function.
- CrCl 10-20 mL/minute: dose as in normal renal function.
- CrCl <10 mL/minute: 250 mg-1 g every 8 hours (maximum 6 g/day in endocarditis).

Intravenous injection

Preparation and administration

See Special handling below.

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

40 | Amoxicillin

- 1. Reconstitute each 250-mg vial with 5 mL WFI (use 10 mL for each 500-mg vial; use 20 mL for each 1-g vial).
- 2. Withdraw the required dose.
- The solution should be clear and a pale straw colour (a transient pink colour or slight opalescence may appear during reconstitution). Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over 3-4 minutes.

Intermittent intravenous infusion

Preparation and administration

See Special handling below.

Amoxicillin is incompatible with Gluc 5%, Hartmann's and KCl.

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Reconstitute each 250-mg vial with 5 mL WFI (use 10 mL for each 500-mg vial; use 20 mL for each 1-g vial).
- 2. Withdraw the required dose and add to a suitable volume of NaCl 0.9% (usually 100 mL).
- 3. The solution should be clear and colourless to pale straw in colour (a transient pink colour or slight opalescence may appear during reconstitution). Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 30-60 minutes.

Intramuscular injection

Preparation and administration

See Special handling below.

- Add 1.5 mL WFI to a 250-mg vial (use 2.5 mL for a 500-mg vial) and shake vigorously. If pain occurs, 1% lidocaine may be used for reconstitution (see the monograph Lidocaine for cautions and monitoring). Do not use the 1-g vial for IM use (two separate 500-mg injections should be given if a 1-g dose is required).
- 2. Withdraw the required dose.
- 3. Give by deep IM injection.

Technical information Incompatible with Amoxicillin is incompatible with Gluc 5%, Hartmann's and KCI. Amikacin, ciprofloxacin, gentamicin, midazolam, tobramycin. Compatible with Flush: NaCl 0.9% Solutions: NaCl 0.9% Y-site: Lorazepam, ofloxacin pH² 8-10 Sodium content 3.3 mmol/1-g vial Storage Store below 25°C in original packaging.

(continued)

Technical information (continued)	
Displacement value	0.2 mL for every 250 mg
Special handling	Avoid skin contact as may cause sensitisation.
Stability after preparation	Reconstituted vials should be used immediately. From a microbiological point of view, prepared infusions should be used immediately; however, they may be stored at 2-8°C and infused (at room temperature) within 24 hours.

Monitoring

Measure	Frequency	Rationale
Renal function	Periodically, especially if for extended duration	 Impaired renal function may occur: consider dose adjustment. Electrolyte disturbances may occur (high Na content).
FBC		• Transient leucopenia, thrombocytopenia, haemolytic anaemia, neutropenia may occur.
Prothrombin time		 Possible prolongation of bleeding time and defective platelet function (monitor closely if anticoagulated).
Signs of supra- infection or superinfection	Throughout treatment	 May result in the overgrowth of non-susceptible organisms: appropriate therapy should be commenced; treatment may need to be interrupted.
Development of diarrhoea	Throughout and up to 2 months after treatment	• Development of severe, persistent diarrhoea may be suggestive of <i>Clostridium difficile</i> -associated diarrhoea and colitis (pseudomembranous colitis). Discontinue drug and treat. Do not use drugs that inhibit peristalsis.
Patency of bladder catheters	Regularly in affected patients	• May precipitate in catheters at high doses.

Additional information

Common and serious undesirable effects	Immediate: Anaphylaxis and other hypersensitivity reactions have been reported. Other: Diarrhoea, nausea, urticaria, maculopapular rashes (often appearing > 7 days after commencing treatment), fever, joint pains and angioedema.
Pharmacokinetics	Elimination half-life is about 1 hour (7-20 hours in severe renal impairment).
Significant interactions	No significant interactions.
Action in case of overdose	Symptoms to watch for: Large doses have been associated with seizures. Antidote: None but haemodialysis may be effective. Stop administration and give supportive therapy as appropriate.

42 | Amoxicillin | Amphotericin

Additional information (continued)		
Counselling	During administration of high doses of amoxicillin maintain adequate fluid intake and urinary output to reduce the possibility of amoxicillin crystalluria. Women taking the combined contraceptive pill should be should be advised to take additional precautions during and for 7 days after the course.	
Risk rating: GREEN	Score = 2 Lower-risk product: Risk-reduction strategies should be considered.	
CONC		
This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Amphotericin (amphotericin B)

See specific preparations on the following pages for injectable forms available.

- Amphotericin is a polyene antifungal.
- It is given by IV infusion in the treatment of severe systemic fungal infections. It is the usual treatment of choice in fungal endocarditis, meningitis, peritonitis, or severe respiratory tract infections. It may be given with flucytosine in severe infections.

Amphotericin is available in four commercial forms and these preparations are **not** interchangeable. They each have specific instructions for reconstitution, test dosing (to check for potential anaphylaxis) and dosing, as stated in the sub-monographs on the following pages. Pre-treatment checks and subsequent monitoring parameters are, however, the same for all.

Pre-treatment checks

- Do not give if there is known hypersensitivity to amphotericin or any excipients, unless in the
 opinion of the physician the advantages of using it outweigh the risks of hypersensitivity.
- Assess sodium status and correct any deficiency before commencing therapy to counter potential amphotericin B-induced nephrotoxicity. Some authorities recommend pre-hydrating with 1 L NaCl 0.9%.

Biochemical and other tests

Bodyweight Electrolytes: serum Na, K, Mg FBC LFTs Renal function: U, Cr, CrCl (or eGFR)

Dose, preparation and administration, technical Information

See the following individual product monographs for Abelcet, AmBisome, Amphocil and Fungizone which all follow this main monograph.

Monitoring		
Measure	Frequency	Rationale
Anaphylactoid reaction	With test dose	 Although anaphylaxis is rare, a test dose followed by 30 minutes of observation is necessary. If a severe allergic reaction occurs no further doses of the preparation should be given. Ensure facilities for cardiopulmonary resuscitation are readily to hand.
Renal function	Daily initially, then two to three times weekly	 ↓K is common. Strategies that have been adopted to counter this include giving spironolactone or amiloride (varying doses have been used). ↓Na may occur but pre-hydrating with 1 L NaCl 0.9% may be sufficient to prevent this. If clinically significant ↓renal function consideration should be given to dose reduction or discontinuation until renal function improves, taking into account any concomitant therapy with known nephrotoxic drugs.
Serum magnesium		• ↓Mg is common and may require supplementation.
LFTs	Weekly	 A clinical decision to discontinue therapy may be needed if abnormal LFTs are observed, i.e. †bilirubin, †Alk Phos.
FBC		 A normocytic anaemia can occur due to suppression of erythropoietin production. If treatment cannot be stopped, blood transfusions or recombinant erythropoietin have been used.
Chills, fever, rigor, nausea and other infusion-related reactions	Observe with each infusion	 Infusion reactions are common. Prophylactic measures should only be advocated when symptoms first arise and then as premedication for subsequent infusions, e.g. Pretreating with paracetamol, antihistamines, antiemetics may lessen these reactions, or running the infusion at a slower rate. An IV dose of 25 mg hydrocortisone is sometimes given before or during the infusion to 1 febrile reactions. Pethidine injection (0.5 mg/kg) has been given in patients likely to develop chills, usually 20 minutes before expected onset of chills. Some centres recommend adding 50 mg pethidine to the infusion bag (<i>Fungizone only</i>). 500-1000 units of heparin sodium is sometimes added to the infusion bag (<i>Fungizone only</i>) to help prevent thrombophlebitis - but not if pethidine is used.

Additional information		
Common and serious undesirable effects	 Immediate: anaphylactoid reactions. Infusion-related: Local: pain and thrombophlebitis at injection site. Other: Common: Headache, ↓K, ↓Mg, ↓Ca, hyperglycaemia, ↓Na, ↑pulse, vasodilatation, flushing, ↓BP, dyspnoea, diarrhoea, abdominal pain, ↑bilirubin, rash, back pain, pyrexia, rigors, chest pain. Rare: Anorexia, nausea and vomiting, diarrhoea, muscle and joint pain; anaemia; renal toxicity; also cardiovascular toxicity (including arrhythmias, BP changes), blood disorders, neurological disorders (including hearing loss, diplopia, convulsions, peripheral neuropathy, encephalopathy), abnormal liver function (see above). 	
Significant interactions	 The following may ↑side-effects with amphotericin: Corticosteroids may ↓K. Acute pulmonary reactions occasionally occur during or shortly after leucocyte transfusions - try to separate these infusions over time as far as possible and monitor pulmonary function. Amphotericin may ↑effect/side-effects of the following drugs: May potentiate the toxicity of digoxin due to ↓K (monitor). May enhance the curariform actions of skeletal muscle relaxants due to ↓K. 	
Action in case of overdose	No specific antidote and not haemodialysable. Monitor cardiorespiratory, ECG, ABG, renal, liver function, haematological status and serum electrolytes and give supportive therapy as required. Correct <i>JBP</i> by raising the foot of the bed and fluid resuscitation.	

Risk rating: RED	Score = 8 High-risk product: Risk-reduction strategies are required to minimise these risks.

Abelcet (amphotericin B-phospholipid complex)

5 mg/mL concentrate for infusion in 20-mL vials

Amphotericin is available in four commercial forms and these preparations are **not** interchangeable. They each have specific instructions for reconstitution, test dosing (to check for potential anaphylaxis) and dosing.

Pre-treatment checks and subsequent monitoring parameters are, however, the same for all and are listed in the main Amphotericin monograph.

Dose

Severe systemic fungal infections in patients not responding to conventional amphotericin or to other antifungal drugs, or where toxicity or renal impairment precludes conventional amphotericin: initial test dose of 1 mg over 15 minutes then 5 mg/kg once daily for at least 14 days.

Intermittent intravenous infusion

Preparation

Check that the prescription specifies Abelcet and that the product you are using is Abelcet. Amphotericin is incompatible with NaCl 0.9% and all electrolyte solutions.

- 1. Allow suspension to reach room temperature then shake gently to ensure there is no yellow sediment at the bottom of the vial.
- 2. Withdraw the required dose (using 17- to 19-gauge needles) into one or more 20-mL syringes.
- 3. Replace the needles on the syringes with a 5-micron filter needle provided by the manufacturer (use a fresh needle for each syringe) and transfer to a suitable volume of Gluc 5% to give a solution containing 1 mg/mL (2 mg/mL can be used in children, patients with cardiovascular disease or patients with fluid restriction).
- The solution should be clear and yellow in colour. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

Administration

- 1. Flush the existing IV line with Gluc 5% (or use a separate line).
- 2. Initial test dose (prior to first dose only): Give 1 mg over 15 minutes via a volumetric infusion device, stop the infusion and observe patient carefully for signs of allergic reactions for at least 30 minutes; if no adverse effects are seen, give the remainder of the infusion.
- 3. Give by IV infusion via a volumetric infusion device at a rate of 2.5 mg/kg/hour (an in-line membrane filter of pore size 15 microns or more may be used).
- 4. Flush line again with Gluc 5% when infusion has finished.

Abelcet - technical information

Incompatible with	Amphotericin is incompatible with NaCl 0.9% and all electrolyte solutions. Amphotericin is incompatible with most drugs; care must be taken to avoid inadvertent contact in infusion lines.
Compatible with	Flush: Gluc 5% Solutions: Gluc 5% Y-site: Not recommended
рН	5-7
Sodium content	Approximately 3 mmol/vial
Storage	Store at 2-8 $^\circ\text{C}$ in original packaging. Do not freeze.
Stability after preparation	From a microbiological point of view, should be used immediately; however, prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours. Shake vigorously before use.
Pharmacokinetics	Elimination half-life is 7 days.

Bibliography

SPC Abelcet (accessed 30 march 2010).

AmBisome (liposomal amphotericin B)

50-mg dry powder vials

Amphotericin is available in four commercial forms and these preparations are **not** interchangeable. They each have specific instructions for reconstitution, test dosing (to check for potential anaphylaxis) and dosing.

Pre-treatment checks and subsequent monitoring parameters are however the same for all and are listed in the main amphotericin monograph.

Dose

Severe systemic or deep mycoses where toxicity (particularly nephrotoxicity) precludes use of conventional amphotericin: initial test dose 1 mg over 10 minutes then 1 mg/kg daily increased gradually if necessary to 3 mg/kg daily; maximum 5 mg/kg daily (unlicensed dose). Suspected or proven infection in febrile neutropenic patients unresponsive to broad-spectrum antibacterials: initial test dose 1 mg over 10 minutes then 3 mg/kg daily until afebrile for three consecutive days; maximum period of treatment 42 days; maximum 5 mg/kg daily (unlicensed dose).

Intermittent intravenous infusion

Preparation

Check that the prescription specifies AmBisome and that the product you are using is AmBisome. Amphotericin is incompatible with NaCl 0.9% and all electrolyte solutions.

- 1. Reconstitute each 50-mg vial with 12 mL WFI.
- Shake the vial vigorously for 30 seconds to completely disperse; the resultant preparation contains 4 mg/mL.
- 3. Visually inspect for particulate matter and continue shaking if necessary.
- 4. Withdraw the required dose and add (via the 5-micron filter provided) to a suitable volume of Gluc 5% to give a solution containing 0.2–2 mg/mL.
- The solution should be clear and yellow in colour. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

Administration

- 1. Flush the existing IV line with Gluc 5% (or use a separate line).
- 2. Initial test dose (prior to first dose only): Give 1 mg over 10 minutes via a volumetric infusion device; stop infusion for 30 minutes and observe patient carefully for signs of allergic reactions; if no adverse effects are seen give the remainder of the infusion.

- 3. Give by IV infusion via a volumetric infusion device over 30–60 minutes (an in-line membrane filter of pore size 1 micron or more may be used). Give doses >5 mg/kg over 2 hours.
- 4. Flush the line again with Gluc 5% when infusion has finished.

AmBisome – technical information		
Incompatible with	Amphotericin is incompatible with NaCl 0.9% and all electrolyte solutions. Amphotericin is incompatible with most drugs; care must be taken to avoid inadvertent contact in infusion lines.	
Compatible with	Flush: Gluc 5% Solutions: Gluc 5% Y-site: Not recommended	
рН	5-6	
Sodium content	< 0.5 mmol/vial	
Storage	Store below 25°C in original packaging. Do not freeze.	
Displacement value	0.5mL/vial but this is already accounted for in the initial reconstitution of the vial	
Stability after preparation	 From a microbiological point of view, should be used immediately; however: Reconstituted vials are single use only but may be stored at 2-8°C for 24 hours. Prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours. 	
Pharmacokinetics	Elimination half-life: 7-10 hours after first dose; 100-153 hours after several doses.	

Bibliography

SPC AmBisome (accessed 30 March 2010).

Amphocil (amphotericin B-sodium cholesteryl sulfate complex)

100-mg and 50-mg dry powder vials

Amphotericin is available in four commercial forms and these preparations are **not** interchangeable. They each have specific instructions for reconstitution, test dosing (to check for potential anaphylaxis) and dosing.

Pre-treatment checks and subsequent monitoring parameters are, however, the same for all and are listed in the main amphotericin monograph.

Dose

Severe systemic fungal infections in patients not responding to conventional amphotericin or to other antifungal drugs, or where toxicity or renal impairment precludes conventional amphotericin: initial test dose 2 mg over 10 minutes then 1 mg/kg daily increased gradually if necessary to 3–4 mg/kg daily. Doses as high as 6 mg/kg daily have been used in some patients.

Intermittent intravenous infusion

Preparation

Check that the prescription specifies Amphocil and that the product you are using is Amphocil. Amphotericin is incompatible with NaCl 0.9% and all electrolyte solutions.

- 1. Reconstitute each vial by rapidly injecting WFI (10 mL for a 50-mg vial; 20 mL for a 100-mg vial)
- Shake gently to until the yellow fluid becomes clear (fluid may be opalescent); the resultant solution contains 5 mg/mL.
- 3. Visually inspect for particulate matter; do not use if any present.
- 4. Withdraw the required dose from the vial(s) and add to a suitable volume of Gluc 5% to give a solution containing 625 micrograms/mL, i.e. add each 1 mL of prepared solution to 7 mL Gluc 5%.
- 5. The solution should be clear and yellow in colour. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

Administration

- 1. Flush the existing IV line with Gluc 5% (or use a separate line).
- 2. Initial test dose (prior to first dose only): Give 3.2 mL (2 mg) of the prepared infusion over 10 minutes via a volumetric infusion device then stop the infusion and observe the patient carefully for signs of allergic reaction for 30 minutes; if no adverse effects are seen give the remainder of the infusion.
- 3. Give by IV infusion at a rate of 1–2 mg/kg/hour via a volumetric infusion device or slower if not tolerated. Amphocil should not be filtered prior to administration and should not be given using an in-line filter.
- 4. Flush line again with Gluc 5% when infusion has finished.

Amphocil – technical information

Incompatible with	Amphotericin is incompatible with NaCl 0.9% and all electrolyte solutions. Amphotericin is incompatible with most drugs; care must be taken to avoid inadvertent contact in infusion lines.
Compatible with	Flush: Gluc 5% Solutions: Gluc 5% Y-site: Not recommended
рН	6.5-7.5
Sodium content	<0.5 mmol/vial
Storage	Store below 30°C in original packaging.
Displacement value	Negligible

(continued)

Amphocil – technical information (continued)	
Stability after preparation	 From a microbiological point of view, should be used immediately; however: Reconstituted vials are single use only but may be stored at 2-8°C for 24 hours. Prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours.
Pharmacokinetics	Elimination half-life is 28-29 hours.

Risk rating: RED	Score = 8 High-risk product: Risk-reduction strategies are required to minimise these risks.

Bibliography

SPCs Amphocil 50 mg and 100 mg (accessed 30 March 2010).

Fungizone Intravenous (conventional amphotericin B)

50-mg (50000 units) dry powder vials

Amphotericin is available in four commercial forms and these preparations are **not** interchangeable. They each have specific instructions for reconstitution, test dosing (to check for potential anaphylaxis) and dosing.

Pre-treatment checks and subsequent monitoring parameters are, however, the same for all and are listed in the main amphotericin monograph.

Dose

Systemic fungal infections: initial test dose of 1 mg by IV infusion over 20–30 minutes, then 250 micrograms/kg by IV infusion once daily, gradually increased over 2–4 days, if tolerated, to 1 mg/kg daily. Generally patients are maintained on the highest dose which is not accompanied by unacceptable toxicity. If there is a gap in therapy of more than 7 days, then the dose must be re-titrated up. **Severe infections**: the daily dose may be increased to a maximum of 1.5 mg/kg either once daily or on alternate days (as the drug is excreted slowly).

Intermittent intravenous infusion

Preparation

Check that the prescription specifies Fungizone and that the product you are using is Fungizone. Amphotericin is incompatible with NaCl 0.9% and all electrolyte solutions.

- 1. The Gluc 5% infusion fluid to be used must be pH 4.2 or above. Check each container and if pH <4.2 add 1-2 mL of a sterile buffer solution*.
- 2. Rapidly add 10 mL WFI to each vial directly into the powder cake using a needle of minimum diameter 20G.
- 3. Shake immediately until clear to produce a 5 mg/mL colloidal solution.
- 4. Withdraw the required dose and add to a suitable volume of Gluc 5% (pH already checked) to give a concentration of 10 mg/100 mL or less. If given via a central line, concentrations up to 40 mg/ 100 mL (unlicensed) have been used.
- 5. The solution should be clear and yellow in colour. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 6. Begin infusion immediately after dilution and protect the infusion container from light throughout administration. It is not necessary to protect giving sets from light as short-term exposure should not affect stability.

*Buffer solution contains: dibasic sodium phosphate (anhydrous) 1.59 g, monobasic sodium phosphate (anhydrous) 0.96 g, WFI to 100 mL.

Administration

- 1. Flush existing IV line with Gluc 5% (or use a separate line).
- 2. Initial test dose (prior to first dose only): Give 1 mg by IV infusion via a volumetric infusion device over 20-30 minutes, stop the infusion and observe patient carefully for signs of allergic reactions for at least 30 minutes; if no adverse effects are seen give the remainder of the infusion.
- 3. Give by IV infusion via a volumetric infusion device over 2-4 hours or longer if not tolerated (an in-line membrane filter of pore size 1 micron or greater may be used).
- 4. Flush line again with Gluc 5% when the infusion has finished.

rungizone infravenous – recinical information		
Incompatible with	Amphotericin is incompatible with NaCl 0.9% and all electrolyte solutions. Amphotericin is incompatible with most drugs; care must be taken to avoid inadvertent contact in infusion lines.	
Compatible with	Flush: Gluc 5% Solutions: Gluc 5% Y-site: Not recommended	
рН	5.7	
Sodium content	<0.5 mmol/vial	
Storage	Store at 2-8°C in original packaging.	
Displacement value	Negligible	
Stability after preparation	 From a microbiological point of view, should be used immediately; however: Reconstituted vials are single use only but may be stored protected from light at 2-8°C for 24 hours. Use prepared infusions immediately and protect from light. 	
Pharmacokinetics	Elimination half-life is 15 days.	

Bibliography

SPC Fungizone intravenous (accessed 30 March 2010).

Ampicillin

500-mg dry powder vials

- · Ampicillin sodium is a penicillin.
- It is used for the treatment of infections including those caused by susceptible Gram-positive organisms. It is sometimes used synergistically with aminoglycoside antibiotics.
- Doses are expressed in terms of ampicillin: Ampicillin 1 g ≈ 1.06 g ampicillin sodium.

Pre-treatment checks

- Do not give if there is known hypersensitivity to penicillins.
- Caution in erythematous rashes common in glandular fever, cytomegalovirus infection, and acute
 or chronic lymphocytic leukaemia.

Biochemical and other tests

FBC LFTs Renal function: U, Cr, CrCl (or eGFR)

Dose

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

Standard dose: 500 mg by IM or IV injection or IV infusion every 4–6 hours. **Listerial meningitis** (in combination with another antibiotic): 2 g by IV infusion every 4 hours for 10–14 days.

52 | Ampicillin

Endocarditis (in combination with another antibiotic if indicated): 2 g by IV infusion every 6 hours, increased to 2 g every 4 hours, e.g. in enterococcal endocarditis or in monotherapy.

Dose in renal impairment: adjusted according to creatinine clearance,¹

- CrCl > 20-50 mL/minute: dose as in normal renal function.
- CrCl 10-20 mL/minute: 250 mg-2 g every 6 hours.
- CrCl <10 mL/minute: 250 mg-1 g every 6 hours.

Intravenous injection

Preparation and administration

See Special handling in Technical information below.

Ampicillin is incompatible with Hartmann's. It is incompatible with Gluc 5% (but may be injected into drip tubing over 3-4 minutes).

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Reconstitute each 500-mg vial with 5 mL WFI.
- 2. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over 3-5 minutes.

Intermittent intravenous infusion

Preparation and administration

See Special handling below.

Ampicillin is incompatible with Gluc 5% and Hartmann's.

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Reconstitute each 500-mg vial with 5 mL WFI.
- 2. Withdraw the required dose and add to a suitable volume NaCl 0.9% (usually 100 mL).
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 30-60 minutes.

Intramuscular injection

Preparation and administration

See Special handling below.

- 1. Add 1.8 mL WFI to a 500-mg vial and shake vigorously to give a solution containing 250 mg/mL.
- 2. Withdraw the required dose.
- 3. Give by deep IM injection.

Technical information			
Incompatible with	Ampicillin is incompatible with Hartmann's. It is incompatible with Gluc 5% (but may be injected into drip tubing over 3-4 minutes). Sodium bicarbonate. Adrenaline (epinephrine), amikacin, amphotericin, calcium gluconate, cisatracurium, dopamine, erythromycin lactobionate, fluconazole, gentamicin, hydralazine, hydrocortisone sodium succinate, metoclopramide, midazolam, ondansetron, tobramycin, verapamil.		
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9% (including added KCl) Y-site: Aciclovir, aztreonam, chloramphenicol sodium succinate, clarithromycin, clindamycin, esmolol, flucloxacillin, furosemide, labetalol, magnesium sulfate, metronidazole, pantoprazole, phytomenadione, propofol, remifentanil, vancomycin		
рН	8-10		
Sodium content	About 1.3 mmol/500-mg vial		
Storage	Store below 25°C		
Displacement value	0.2 mL/500 mg		
Special handling	Avoid skin contact as may cause sensitisation.		
Stability after preparation	Reconstituted vials should be used immediately. From a microbiological point of view, prepared infusions should be used immediately; however, they may be stored at 2-8°C and infused (at room temperature) within 24 hours.		

Monitoring

Measure	Frequency	Rationale
Renal function	Periodically, especially if for extended duration	 Impaired renal function may occur: may require a dose adjustment. Electrolyte disturbances may occur (high Na content).
FBC		 Transient leucopenia, thrombocytopenia, haemolytic anaemia, neutropenia may occur.
Prothrombin time		 Possible prolongation of bleeding time and defective platelet function (monitor closely if anticoagulated).
LFTs		 Moderate
Development of diarrhoea	Throughout and up to 2 months after treatment	 Development of severe, persistent diarrhoea may be suggestive of <i>Clostridium difficile</i>-associated diarrhoea and colitis (pseudomembranous colitis). Discontinue drug and treat. Do not use drugs that inhibit peristalsis.
54 | Ampicillin

Monitoring (continued)			
Measure	Frequency	Rationale	
Signs of supra- infection or superinfection	Throughout treatment	 May result in the overgrowth of non-susceptible organisms - appropriate therapy should be commenced; treatment may need to be interrupted. 	
Development of rash		 A maculopapular rash sometimes occurs (often appearing more than 7 days after commencing treatment), which may or may not be related to a hypersensitivity reaction. In practice clinicians discontinue if this occurs. It should preferably not be given to patients with infectious mononucleosis since they are especially susceptible to ampicillin-induced skin rashes. 	
Additional infor	mation		
Common and serious undesirable effects	Immediate: Anaphylaxis and other hypersensitivity reactions have been reported. Other: Diarrhoea, nausea, urticaria, maculopapular rashes (often appearing > 7 days after commencing treatment), fever, joint pains and angioedema.		
Pharmacokinetics	Elimination half-life is 1-1.9 hours.		
Significant interactions	No significant interactions.		
Action in case of overdose	Symptoms to watch for: Large doses have been associated with seizures. Antidote: None, haemodialysis may be effective. Stop administration and give supportive therapy as appropriate.		
Counselling	Women taking the combined contraceptive pill should be should be advised to take additional precautions during and for 7 days after the course.		

Risk rating: GREEN	Score = 2 Lower-risk product: Risk-reduction strategies should be considered.			
CONC				
This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Anidulafungin

100-mg dry powder vials

- Anidulafungin is a semi-synthetic echinocandin antifungal agent active against *Aspergillus* and *Candida* spp.
- It is used in the treatment of candidaemia, oesophageal candidiasis and other forms of invasive candidiasis.

Pre-treatment checks

Do not give if there is known hypersensitivity to any echinocandin-class medicines.

Biochemical and other tests

Fungal culture (unknown causative organism does not prevent empirical treatment). LFTs

Dose

Treatment of invasive candidiasis in adult non-neutropenic patients: 200 mg by IV infusion on the first day, then 100 mg by IV infusion daily. The duration of therapy should be based on the patient's clinical response and usually continues for at least 14 days after the last positive culture.

Intermittent intravenous infusion

Preparation and administration

NB: Anidulafungin was previously available as a dry powder vial accompanied by an ethanolcontaining solvent. The preparation instructions are different for that product.

- 1. Reconstitute each vial with 30 mL WFI (this can take up to 5 minutes). The reconstituted solution must be further diluted within 1 hour.
- Withdraw the entire contents of each vial to be used and add to 100 mL NaCl 0.9% or Gluc 5% (i.e. if giving a 200-mg dose, use two 100-mL bags). Each bag now contains 130 mL.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give each bag by IV infusion over a minimum of 90 minutes, i.e. give each bag at a maximum rate of 87 mL/hour. If giving a 200-mg dose give the bags one after the other.

Bibliography

SPC ECALTA 100 mg powder for concentrate for solution for infusion (accessed 9 March 2010).

Apomorphine hydrochloride

10 mg/mL solution in 2-mL and 5-mL ampoules, 3-mL pen injector 5 mg/mL solution in 10-mL pre-filled syringe (for infusion only)

Apomorphine should be used under specialist supervision only.

- Apomorphine is a dopamine agonist.
- It is used in Parkinson disease to treat disabling motor fluctuations (or the 'on-off' phenomenon) where treatment with levodopa (plus peripheral decarboxylase inhibitor) and/or other dopamine agonists has diminished. It may be used for long-term treatment in advanced disease, or as a palliative treatment near the end of life.

Pre-treatment checks

- Do not give to patients with respiratory depression, dementia, psychotic diseases or hepatic impairment.
- Do not give to patients who have an 'on' response to levodopa that is marred by severe dyskinesia or dystonia.
- Ensure that the patient has been initiated on domperidone (usually 20 mg three times a day) at least 2 days before therapy begins (nausea and vomiting occurs in up to 10% of patients, particularly at initiation). It may be possible to reduce or withdraw domperidone altogether once treatment is established.
- · Caution in renal, pulmonary or cardiovascular disease and in patients prone to nausea and vomiting.

Biochemical and other tests

Blood pressure ECG if there are any cardiovascular disorders FBC – screen for haemolytic anaemia LFTs Renal function: U, Cr, CrCl (or eGFR)

Dose

Initiation of therapy (in hospital):

- When the patient has received domperidone 20 mg three times a day for at least 2 days, withhold existing antiparkinsonian medication overnight to provoke an 'off' episode.
- To determine the threshold dose give 1 mg (0.1 mL) by SC injection and observe for 30 minutes for a
 motor response. If there is no response or an inadequate response, give 2 mg by SC injection and
 observe for an additional 30 minutes. Continue to increase the dose in an incremental manner,
 leaving a minimum of 40 minutes between injections until a satisfactory motor response is obtained.

Maintenance therapy:

- The previously determined dose (maximum recommended single dose 10 mg) may be given at the first signs of an 'off' episode. Absorption may vary with different injection sites so observe for 60 minutes to assess quality of response.
- The usual daily dose varies according to the patient's response, but is typically in the range of 3–30 mg given as 1–10 injections/day (sometimes as many as 12). The maximum recommended daily dose is 100 mg.

Continuous infusion:

- Used for patients who have shown a good 'on' response but whose overall control remains unsatisfactory using intermittent injections or who require more than 10 injections/day.
- Start at 1 mg/hour by SC infusion and increase in increments of not more than 0.5 mg/hour leaving a minimum of 4 hours between increases. Usual rate is 1–4 mg/hour. Additional intermittent injections may be given if required.
- Continuous infusions are normally given during the patient's waking hours. 24-hour infusions are not recommended unless there are severe night time problems.

Subcutaneous injection (intermittent injection)

- 1. Withdraw the required dose from an ampoule, or if using the pen injector set the dose in accordance with the manufacturer's instructions.
- 2. The solution should be clear and colourless; do not use if the solution has turned green or if particles can be seen.
- 3. Give by SC injection into the lower abdomen or outer thigh. Rotate sites for subsequent injections.

Subcutaneous infusion (continuous infusion)

Apomorphine injection must not be given by the IV route. Do not mix with WFI – this can lead to nodule formation and ulceration.

Preparation and administration

- 1. Withdraw the required dose using ampoules or the 5 mg/mL pre-filled syringe.
- If using 10 mg/mL ampoules the solution may be diluted with an equal volume of NaCl 0.9% before administration to reduce local SC reactions.
- 3. The solution should be clear and colourless; do not use if the solution has turned green or if particles can be seen.
- 4. Give by continuous SC infusion by a mini pump or syringe driver, changing the infusion site every 12 hours.

Technical information

Aripiprazole

7.5 mg/mL solution in 1.3-mL vial

- Aripiprazole is an atypical antipsychotic.
- It is used IM for the rapid control of agitation and disturbed behaviour in patients with schizophrenia or mania when oral therapy is not appropriate.

Pre-treatment checks

- Review physical health; aripiprazole should be used with caution in patients with cerebrovascular disease, conditions that would predispose patients to JBP (dehydration, hypovolaemia, and treatment with antihypertensive medications) or *fBP*, including accelerated or malignant.
- Caution should be taken if patient is already taking medication which is known to cause QT prolongation or electrolyte imbalance.
- Seizures are rare with aripiprazole but it should be used with care in those with a history of seizures
 or with conditions that lower the seizure threshold.
- Consider medication already administered for maintenance or acute treatment of schizophrenia or mania.

Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure	Pulse
ECG	Respiratory rate

Dose

Initial dose: usual dose is 9.75 mg (1.3 mL) by IM injection, although the effective dose range is 5.25–15 mg (0.7–2 mL).

Further doses: if required a second injection may be given 2 hours after the first injection but no more than three injections should be given in any 24-hour period. The maximum daily dose is 30 mg by all routes.

Patients should be switched to oral therapy as soon as possible if ongoing treatment is required.

Intramuscular injection

- 1. Withdraw the required dose.
- 2. Give by IM injection into the deltoid muscle or deep within the gluteus maximus muscle.

Bibliography

SPC Abilify (accessed 15 April 2009).

Ascorbic acid (vitamin C)

500 mg/5 mL solution ampoule

- Ascorbic acid and its calcium and sodium salts have vitamin C activity. Vitamin C is a watersoluble vitamin essential for the synthesis of collagen and intercellular material.
- Deficiency leads to the development of scurvy characterised by capillary fragility, bleeding (especially from small blood vessels and the gums), normocytic or macrocytic anaemia, cartilage and

62 | Ascorbic acid

bone lesions, and slow healing of wounds. Deficiency develops when dietary intake is inadequate and may occur in infants and alcoholics. It is rare in adults, but less florid manifestations of vitamin C deficiency are commonly found, particularly in elderly patients.

 Patients taking high-dose ascorbic acid for prolonged periods may become tolerant to it and exhibit symptoms of deficiency when intake is reduced to normal.

Pre-treatment checks

- Large doses can cause haemolysis in patients with G6PD deficiency.
- Large doses may cause hyperoxaluria and renal oxalate calculi. This is more likely in dehydrated individuals.

Dose

Ascorbic acid is usually given orally. If oral administration is not feasible or when malabsorption is suspected, utilisation is reportedly better after IM administration.

For scurvy: 250 mg (parenteral) once or twice daily should reverse skeletal changes and haemorrhagic disorders within 2–21 days.

Prevention of scurvy: 50-200 mg daily (oral or parenteral).

Intramuscular injection (preferred route if parenteral administration is necessary)

Preparation and administration

- 1. Withdraw the required dose.
- Inject slowly high into the gluteal muscle, 5 cm below the iliac crest. Rotate injection sites for subsequent injections.

Intermittent intravenous infusion

Preparation and administration

- 1. Withdraw the required dose and add to 100 mL NaCl 0.9% or Gluc 5%.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 15-30 minutes.

Subcutaneous injection

- 1. Withdraw the required dose.
- 2. Give by SC injection.

Technical information			
Incompatible with	Aminophylline, benzylpenicillin, chloramphenicol sodium succinate, doxapram, erythromycin lactobionate, hydrocortisone sodium succinate, propofol, sodium bicarbonate.		
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, Gluc-NaCl, Hartmann's, Ringer's Y-site: Amikacin, calcium gluconate, metoclopramide, verapamil		
рН	5.5-6.5		

Technical information (continued)				
Sodium content	Ne	egligible		
Excipients	Contains sulfites (may		y cause allergic reactions).	
Storage	Sto	ore below 25°C in	original packagi	ng.
Stability after preparation	Fra ho ter	From a microbiological point of view, should be used immediately; however, prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours.		
Monitoring				
Measure		Frequency		Rationale
Fluid balance	Regularly during		g treatment	 Dehydration increases the likelihood of renal oxalate calculi formation.
Ability to urinate		Daily		• High-dose ascorbic acid can cause renal oxalate calculi.
Additional information	ion			
Common and serious undesire	able	effects	Large doses of ascorbic acid have resulted in haemolysis in G6PD deficiency.	
Pharmacokinetics			Ascorbic acid is widely distributed in the body tissues. Doses in excess of the body's needs are rapidly eliminated unchanged in the urine; this generally occurs with intakes exceeding 100 mg daily.	
Significant interactions			 Ascorbic acid should not be given for the first month after starting desferrioxamine as it can initially worsen iron toxicity. Ascorbic acid may interfere with a number of tests based on oxidation-reduction reactions. 	
Action in case of overdose			Stop treatment and give supportive therapy as appropriate.	

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Atenolol

500 micrograms/mL solution in 10-mL ampoules

- · Atenolol is a cardioselective beta-adrenoceptor blocker.
- It is used IV for the early management of suspected acute myocardial infarction within 12 hours of
 onset of chest pain, and in management of arrhythmias.

Pre-treatment checks

- Atenolol is likely to worsen pre-existing uncontrolled heart failure, ↓BP, bradyarrhythmias or
 obstructive airways disease and the risk/benefits should be considered before use.
- Use with extreme caution in asthmatics.
- · Dosage requirements may be reduced in patients with impaired renal function.

Biochemical and other tests

Blood pressure	Pulse
Bodyweight (for infusion)	Renal function: U, Cr, CrCl (or eGFR)

Dose

Myocardial infarction: 5 mg (10 mL) by IV injection followed by oral beta-blocker therapy as appropriate.

Cardiac arrhythmias, by IV injection: 2.5 mg (5 mL) by IV injection. This dose may be repeated at 5-minute intervals until an adequate response is attained, up to a maximum dosage of 10 mg. The cumulative dose can be repeated every 12 hours until oral beta-blocker therapy is appropriate.

Cardiac arrhythmias, by IV infusion: 150 micrograms/kg by intermittent IV infusion. Required dose of atenolol injection in mL: (150 micrograms/kg) = bodyweight (kg) \times 0.3. This dose can be repeated every 12 hours until oral beta-blocker therapy is appropriate.

Intravenous injection

Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection at a maximum rate of 1mg/minute (2 mL/minute).

Intermittent intravenous infusion

- 1. Withdraw the required dose.
- 2. Add to a suitable volume (usually 100 mL) of NaCl 0.9% or Gluc 5%.

- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 20 minutes.

Technical inform	ation				
Incompatible with	Amphotericin				
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9% Y-site: Meropenem, m	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, Gluc-NaCl Y-site: Meropenem, morphine sulfate			
рН	5.5-6.5				
Sodium content	Negligible				
Storage	Store below 25°C in or	riginal packaging.			
Stability after preparation	From a microbiological point of view, should be used immediately; however, prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours.				
Monitoring					
Measure	Frequency	Rationale			
Pulse	Continuously	 Consider withholding therapy if pulse drops to 50-55 bpm or lower. Excessive pulse can be countered with IV atropine sulfate in doses of 600 micrograms repeated every 3-5 minutes up to a maximum of 2.4 mg. 			
Blood pressure		 Stop dosing if ↓BP occurs that requires corrective measures. 			
Respiratory function or oxygen saturation in at risk individuals	 After initial dosing May cause bronchoconstriction in susceptindividuals, e.g. patients with history of bronchospasm or respiratory disease. 				
Additional infor	mation				
Common and serious undesirable effects	 ↓Pulse, ↓BP, cold extremities. Bronchospasm may occur in patients with asthma or other respiratory disease. 				
Pharmacokinetics	Approximately 6 hours (longer in renal impairment)				
Significant interactions	 The following may <i>î</i> atenolol levels or effect (or <i>î</i> side-effects): adrenaline (risk of severe <i>î</i>BP and <i>i</i> pulse), alpha-blockers (severe <i>i</i>BP), amiodarone (risk of <i>i</i> pulse and AV block), antiarrhythmics (risk of myocardial depression), clonidine (<i>î</i> risk of withdrawal <i>î</i>BP), diltiazem (risk of <i>i</i> pulse and AV block), dobutamine (risk of severe <i>î</i>BP and <i>i</i> pulse), flecainide (risk of myocardial depression and <i>i</i> pulse), moxisylyte (severe <i>i</i>BP), nifedipine (severe <i>i</i>BP and heart failure), noradrenaline (risk of severe <i>î</i>BP and <i>i</i> pulse), verapamil (risk of asystole and severe <i>i</i>BP). 				

Additional information (continued)				
 Symptoms to watch for: ↓Pulse, ↓BP, acute cardiac insufficiency and bronchospasm. Antidate: Excessive ↓pulse can be countered with IV atropine sulfate (see Monitoring above and the Atropine sulfate monograph). Glucagon or dobutamine are further options for unresponsive ↓pulse - seek specialist advice. Bronchospasm can usually be reversed by bronchodilators. 				
Patients may experience fatigue and cold extremities during maintenance therapy, and should report wheezing.				

Risk rating: AMBER	Score = 3 Moderate-risk product: Risk-reduction strategies are recommended.

Bibliography

SPC Tenormin (accessed 5 January 2009).

Atosiban

6.75 mg/0.9 mL solution in vials

7.5 mg/mL solution in 5-mL vials

- Atosiban is a peptide analogue of oxytocin, which acts as an oxytocin receptor antagonist.
- It is used to delay imminent uncomplicated premature labour presenting at 24–33 weeks' gestation.
- · Atosiban is given IV as the acetate, but doses are expressed in terms of the base.

Pre-treatment checks

- Contraindicated in eclampsia and severe pre-eclampsia, intrauterine infection, intrauterine fetal death, antepartum haemorrhage (requiring immediate delivery), placenta praevia, abruptio placenta, intrauterine growth restriction with abnormal fetal heart rate, premature rupture of membranes after 30 weeks' gestation.
- Atosiban is not licensed for use in any conditions of the mother or fetus in which continuation of
 pregnancy is hazardous, so a full examination of mother and fetus should be carried out to ensure
 that the presentation is uncomplicated.

Biochemical and other tests

Cervical dilatation $(1-3 \text{ cm}, \text{ or } 0-3 \text{ cm} \text{ for} women who have not previously given birth), cervical effacement (<math>\geq 50\%$).

Gestational age (from 24 to 33 completed weeks).

LFTs (there is insufficient clinical trial data to support use in hepatic impairment, so caution is advised). Patient age (≥ 18 years).

Rate and duration of uterine contractions (minimum 30 seconds duration at a rate of \geq 4 per 30 minutes).

Renal function: U, Cr, CrCl (or eGFR) (there is insufficient clinical trial data to support use in renal impairment, so caution is advised).

Dose

Treatment is divided into three stages:

- 1. An initial dose of 6.75 mg/0.9 mL is given by IV injection over 1 minute.
- 2. A loading dose of 300 micrograms/minute is given by IV infusion for 3 hours.
- A further 100 micrograms/minute by IV infusion is given for up to 45 hours. The total duration of treatment should not exceed 48 hours, and the total dose of atosiban should not exceed 330 mg per course of treatment.

Intravenous injection

Preparation and administration

- 1. Using the 6.75 mg/0.9 mL vial withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 1 minute.

Intravenous infusion

Preparation

- 1. Remove 10 mL from a 100-mL bag of NaCl 0.9% or Gluc 5% and discard.
- Using two 5-mL vials withdraw 75 mg (10 mL) of atosiban and add to the prepared infusion bag. Mix well to give a solution containing atosiban 750 micrograms/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

Administration

- 1. Give by IV infusion using a volumetric infusion device at a rate of 24 mL/hour (18 mg/hour) for the 3-hour loading period.
- 2. Reduce the rate of infusion to 8 mL/hour (6 mg/hour) for up to 45 hours as required.
- 3. Prepare replacement infusion bags as necessary to ensure that the infusion can continue to run.

Technical information	
Incompatible with	No information
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, Hartmann's Y-site: No information

68 | Atosiban

Technical information (continued)				
Sodium content	Nil			
Storage	Store at 2-8°C in original packaging. Use opened vials immediately and discard any unused solution.			
Stability after preparation	From a microbiological point of view, should be used immediately; however, prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours.			

Monitoring

Measure	Frequency	Rationale
Physical evidence of labour	Throughout infusion	 E.g. cervical examination, uterine contractions via external tocodynamometry. Discontinuation is warranted if cervical dilatation of ≥1 cm occurs during therapy, or if contractions continue for 6 hours.
Maternal blood pressure and heart rate		 Atosiban infusion can cause \BP and \pulse. ECG monitoring should be carried out in patients with pre-existing cardiovascular disease, or in any patients exhibiting cardiac symptoms during infusion.
Maternal blood glucose level		Atosiban infusion can cause hyperglycaemia.
Fetal heart rate		• To monitor for signs of distress.
Postpartum blood loss	Postpartum	 As an oxytocin antagonist, atosiban may facilitate increased postpartum blood loss due to uterine relaxation.

Additional information

Common and serious undesirable effects	Injection/infusion-related: Local: Injection-site reactions. Other: Nausea, vomiting, hyperglycaemia, headache, dizziness, ↑pulse, ↓BP, hot flushes, insomnia, pruritus, rash, pyrexia.
Pharmacokinetics	Elimination half-life is 1.7 hours.
Significant interactions	No significant interactions.
Action in case of overdose	No specific signs or symptoms reported. No known specific treatment.
Counselling	Small amounts of atosiban and an active metabolite have been found to be present in breast milk. No known adverse effects in neonates.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Bibliography

SPC Tractocile 7.5 mg/mL concentrate for solution for infusion (accessed 1 October 2009). SPC Tractocile 7.5 mg/mL solution for injection (accessed 1 October 2009).

Atropine sulfate

600 micrograms/mL solution in ampoules and pre-filled syringes (other strengths available)

100 micrograms/mL and 200 micrograms/mL solution in pre-filled syringes of various sizes

- Atropine sulfate is an antimuscarinic alkaloid with both central and peripheral actions. It has
 antispasmodic actions on smooth muscle and reduces salivary and bronchial secretions. It
 depresses the vagus and thereby increases the heart rate.
- It is used preoperatively to reduce secretions; during CPR to treat sinus bradycardia or asystole; to treat symptomatic sinus bradycardia induced by drugs or toxic substances; to prevent muscarinic effects on the heart (e.g. arrhythmias, \pulse) during surgery and in combination with neostigmine or edrophonium during reversal of effect of non-depolarising muscle relaxants.

Pre-treatment checks

- Contraindications are not applicable to the use of atropine in life-threatening emergencies (e.g. asystole).
- Atropine is contraindicated in obstruction of the bladder neck, e.g. due to prostatic hypertrophy, reflux oesophagitis, closed-angle glaucoma, myasthenia gravis (unless used to treat the adverse effects of an anticholinesterase agent), paralytic ileus, severe ulcerative colitis and obstructive disease of the GI tract.
- Caution in patients with hyperthyroidism, hepatic or renal disease or hypertension; febrile
 patients or when ambient temperature is high since antimuscarinics may cause an increase in
 temperature.
- Antimuscarinics block vagal inhibition of the SA (sinoatrial) nodal pacemaker and should thus be used with caution in patients with tachyarrhythmias, congestive heart failure or coronary heart disease.
- Parenterally administered atropine should be used cautiously in patients with chronic pulmonary disease since a reduction in bronchial secretions may lead to formation of bronchial plugs.
- Extreme caution is required in patients with autonomic neuropathy.
- Antimuscarinics decrease gastric motility, relax the lower oesophageal sphincter and may delay
 gastric emptying; they should therefore be used with caution in patients with gastric ulcer, oesophageal reflux or hiatus hernia associated with reflux oesophagitis, diarrhoea or GI infection.

Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure	LFTs
Heart rate	Renal function: U, Cr, CrCl (or eGFR)

Dose

Premedication: 300–600 micrograms by IV injection immediately before induction of anaesthesia or 300–600 micrograms by SC or IM injection 30–60 minutes before induction.

Intraoperative bradycardia: 300–600 micrograms (larger doses in emergencies) by IV injection. **Control of muscarinic side-effects of neostigmine or edrophonium in reversal of competitive neuromuscular block**: 600 micrograms–1.2 mg by IV injection.

Bradycardia of acute myocardial infarction: 500 micrograms by IV injection repeated every 3– 5 minutes to a total dose of 3 mg. (If IV access cannot be obtained, consider the endotracheal route.) **In CPR for asystole**: 3 mg as a single IV dose. (If IV access cannot be obtained, consider the intraosseous route or the endotracheal route.)

Intravenous injection

Preparation and administration

- 1. Withdraw the required dose or select the appropriate pre-filled syringe.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give rapidly by IV injection (slow IV injection may cause paradoxical slowing of the heart).

Subcutaneous injection

Preparation and administration

- 1. Withdraw the required dose or select the appropriate pre-filled syringe.
- 2. Give by SC injection.

Intramuscular injection

Preparation and administration

- 1. Withdraw the required dose or select the appropriate pre-filled syringe.
- 2. Give by IM injection.

Endotracheal administration

Preparation and administration

- 1. Withdraw the required dose (2-3 times the IV dose is given by this route).
- 2. Dilute the dose with 10 mL WFI or NaCl 0.9%.
- 3. Administer via the endotracheal tube.

Technical information					
Incompatible with	Flucloxacillin, pantoprazole.				
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5% (with added KCl) Y-site: Dobutamine, fentanyl, furosemide, hydrocortisone sodium succinate, meropenem, metoclopramide, midazolam, ondansetron, ranitidine, verapamil				
рН	3-6.5				

Technical information (continued)					
Sodium content	Negligible	Negligible			
Storage	Store belov	w 25°C in or	iginal packaging. Do not freeze.		
Monitoring					
Measure	Frequenc	у	Rationale		
Clinical improvement	Periodicall	у	• To ensure that treatment is effective.		
Additional infor	mation				
Common and serious undesirable effects	Injection-re damage. Other: [Pu depression blurred vis		elated: Local: extravasation may cause tissue Ilse, cardiac dysrhythmias, coma, respiratory 1, †intraocular pressure, constipation, dry mouth, iion, light intolerance, urinary retention.		
Pharmacokinetics		Following IV administration, the peak increase in her within 2-4 minutes. After IM administration peak effi heart, sweating and salivation occur after ~1 hour. half-life is 2-5 hours.			
Significant interactions		No significant interactions.			
Action in case of overdose Antida and c should Antia occur		Antidote: I and convu should be Antiarrhyth occur.	Diazepam may be administered to control excitement lsions but the risk of central nervous system depression considered. amic drugs are <i>not</i> recommended if dysrhythmias		

Risk rating: GREEN	Score = 1 Moderate-risk product: Risk-reduction strategies are recommended.					

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Azathioprine

50-mg dry powder vials

- Azathioprine is an immunosuppressive anti-metabolite with actions similar to those of mercaptopurine, to which it is converted in the body.
- It is used to suppress rejection in organ transplant recipients and to treat a variety of chronic inflammatory and autoimmune diseases. Its effects may not be seen for several weeks after a dose.

Pre-treatment checks

- Do not use if there is hypersensitivity to azathioprine or mercaptopurine.
- · Caution in renal and hepatic impairment.

Biochemical and other tests

Bodyweight FBC LFTs Renal function: U, Cr, CrCl (or eGFR)

Dose

Azathioprine injection is alkaline and very irritant and it should only be used when the oral route is impractical; therapy should be switched back to the oral route as soon as it is tolerated.

Consult specialist literature: the starting and maintenance doses vary depending on the indication; e.g. in transplantation the first dose can be up to 5 mg/kg/day and maintenance doses range from 1 to 4 mg/kg/day. For autoimmune conditions maintenance doses are usually 1–3 mg/kg/day. **Dose in renal impairment**: adjusted according to creatinine clearance,¹

- CrCl >20-50 mL/minute: dose as in normal renal function.
- CrCl 10-20 mL/minute: 75-100% of dose for normal renal function.
- CrCl <10 mL/minute: 50-100% of dose for normal renal function.

Dose in hepatic impairment: use doses at the lower end of the range.

Intermittent intravenous infusion (preferred method)

See Special handling and Spillage below.

- 1. Reconstitute each 50-mg vial with 5 mL WFI to give a solution containing 10 mg/mL.
- Withdraw the required dose and add to a suitable volume of NaCl 0.9% or Gluc 5% (usually 100 mL but up to 200 mL may be used).
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion via a volumetric infusion device over 30-60 minutes.
- 5. Discard any unused portion in accordance with local protocols.

Intravenous injection (avoid if possible – use only where dilution is not practicable)

See Special handling and Spillage below.

- 1. Reconstitute each 50-mg vial with 5 mL WFI to give a solution containing 10 mg/mL.
- 2. Withdraw the required dose and further dilute to 20 mL with NaCl 0.9%.
- 3. The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection slowly over 3–5 minutes (and not less than 1 minute), taking care to avoid extravasation.
- 5. Follow immediately with a flush of at least 50 mL NaCl 0.9%.
- 6. Discard any unused portion in accordance with local protocols.

Technical information				
Incompatible with	No information			
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc-NaCl, Gluc 5% Y-site: No information			
рН	Reconstituted: 10-12; more dilute inf	usion solutions have a lower pH.		
Sodium content	Negligible			
Storage	Store below 25°C in original packag	jing.		
Displacement value	Negligible			
Special handling	Follow local guidelines for the handling of cytotoxic drugs.			
Spillage	Inactivate any spills using sodium hypochlorite 5% solution (household bleach), or sodium hydroxide solution.			
Stability after preparation	From a microbiological point of view, should be used immediately; however: Reconstituted vials may be stored at 5-8°C for 24 hours. Prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours.			
Monitoring				
Measure	Frequency	Rationale		
FBC	Weekly for first 8 weeks (more frequently if there is renal/	• Bone marrow suppression can occur.		
LFTs	hepatic impairment), then monthly (or not more than 3-	 Dose may need adjusting if hepatic function changes. 		
Renal function	monninyj	 Dose may need adjusting if renal function changes. 		
Any infection, unexpected bruising or bleeding	d Counsel patient to seek medical advice if these are present	• Symptoms of bone marrow suppression.		

Additional information		
Common and serious undesirable effects	Viral, fungal and bacterial infections; leucopenia; thrombocytopenia.	
Pharmacokinetics	Elimination half-life is 4-6 hours.	
Significant interactions	 The following may ↑azathioprine levels or effect (or ↑side-effects): allopurinol (give 25% of usual azathioprine dose), co-trimoxazole (↑risk of haematological toxicity), trimethoprim (↑risk of haematological toxicity). Azathioprine may ↓levels or effect of coumarin anticoagulants (monitor INR). 	
Action in case of overdose	No specific antidote. It is partially dialysable (although the value of this is unknown). Haematological monitoring is necessary to allow prompt treatment of any adverse effects that may develop (e.g. blood and platelet transfusion, antibiotics).	
Counselling	Exposure to sunlight and UV light should be limited as patients taking azathioprine have †risk of skin cancer. Patients should wear protective clothing and use a high protection factor sunscreen.	

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Bibliography

SPC Imuran injection (accessed 2 March 2010).

Aztreonam

500-mg, 1-g, 2-g dry powder vials

- Aztreonam is a synthetic monocyclic beta-lactam (monobactam) antibiotic and acts similarly to the penicillins.
- It is used to treat Gram-negative infections (including beta-lactamase-producing strains) particularly *Pseudomonas aeruginosa, Haemophilus influenzae* and *Neisseria meningitidis*.

Pre-treatment checks

- Do not give in pregnancy.
- · Caution in hypersensitivity to other beta-lactam antibiotics; hepatic impairment; renal impairment.

Biochemical and other tests (not all are necessary in an emergency situation)

FBC	Prothrombin time in certain circumstances
LFTs	Renal function: U, Cr, CrCl (or eGFR)

Dose

Standard dose: 1 g by IM or IV injection or IV infusion every 6–8 hours, or 2 g by IV injection or infusion every 12 hours.

Severe or life-threatening infections (including systemic *Pseudomonas aeruginosa* and lung infections in cystic fibrosis): 2 g by IV injection or infusion every 6–8 hours.

Urinary tract infections: 500 mg-1 g by IM or IV injection or IV infusion every 8-12 hours.

Gonorrhoea/cystitis: 1 g single dose by IM injection.

Dose in renal impairment: adjusted according to creatinine clearance,¹

- CrCl >30-50 mL/minute: dose as in normal renal function.
- CrCl 10-30 mL/minute: 1-2 g loading dose then maintenance of 50% of appropriate normal dose.
- CrCl <10 mL/minute: 1-2 g loading dose then maintenance of 25% of appropriate normal dose.

Intravenous injection

Preparation and administration

- 1. Add 6-10 mL WFI to each vial. Shake immediately and vigorously.
- 2. Withdraw the required dose.
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over 3-5 minutes.

Intermittent intravenous infusion

Preparation and administration

- 1. Add 10 mL WFI to each vial. Shake immediately and vigorously.
- Withdraw the required dose and add to a suitable volume of NaCl 0.9% or Gluc 5% (add each 1 g to at least 50 mL).
- 3. The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 20-60 minutes.

Intramuscular injection (maximum dose 1 g)

- 1. Add 1.5 mL WFI or NaCl 0.9% to a 500-mg vial (use 3 mL for a 1-g vial). Shake immediately and vigorously.
- 2. Withdraw the required dose. The solution should be clear and colourless to pale yellow. Visually inspect for particulate matter and discoloration and discard if present.
- 3. Give by deep IM injection, e.g. into the upper quadrant of the gluteus maximus or the lateral part of the thigh.

Technical inform	ation
Incompatible with	Aciclovir, amphotericin B, ampicillin, ganciclovir, metronidazole, vancomycin.
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, Gluc-NaCl, Hartmann's, Ringer's (all including added KCl) Y-site: Amikacin, aminophylline, bumetanide, calcium gluconate, cefotaxime, ceftazidime, ceftriaxone, cefuroxime, ciprofloxacin, cisatracurium, clindamycin, co-trimoxazole, dexamethasone, dobutamine, dopamine, fluconazole, furosemide, gentamicin, granisetron, hydrocortisone sodium succinate, imipenem with cilastatin, magnesium sulfate, methylprednisolone sodium succinate, metoclopramide, piperacillin with tazobactam, propofol, ranitidine, remifentanil, sodium bicarbonate, ticarcillin with clavulanate, tobramycin
рН	4.5-7.5
Sodium content	Nil
Excipients	Contains Larginine (may cause hypersensitivity reactions).
Storage	Store below 25°C in original packaging.
Displacement value	0.4 mL/500 mg
Stability after preparation	Reconstituted vials should be used immediately. From a microbiological point of view, prepared infusions should be used immediately; however, they may be stored at 2-8°C and infused (at room temperature) within 24 hours. Solutions may develop a slight pink tint on standing without potency being affected.

Monitoring

Measure	Frequency	Rationale
Renal function	Periodically	 Transient rises in urea and creatinine occur rarely. If renal function changes a dose adjustment may be required.
FBC		 Transient eosinophilia may occur in up to 11%. Occasional leucopenia, neutropenia, thrombocytopenia, pancytopenia, anaemia, leucocytosis and thrombocytosis have been reported.
LFTs		 Jaundice and hepatitis have occurred. Transient ↑ALT, AST and Alk Phos may occur.
Prothrombin time		 Prolongation of bleeding time and defective platelet function may occur (monitor closely if anticoagulated).
Signs of supra- infection or superinfection	Throughout treatment	 May result in the overgrowth of non-susceptible organisms - appropriate therapy should be commenced; treatment may need to be interrupted.

Aztreonam 77

Monitoring (continued)			
Measure	Frequency	Rationale	
Development of diarrhoea	Throughout and up to 2 months after treatment	 Development of severe, persistent diarrhoea may be suggestive of <i>Clostridium difficile</i>-associated diarrhoea and colitis (pseudomembranous colitis). Discontinue drug and treat. Do not use drugs that inhibit peristalsis. 	
Additional information			
Common and serious undesirable effects	Immediate: Anaphylaxis and other hypersensitivity reactions have been reported. Injection/infusion-related: Local: Phlebitis at IV injection site, discomfort at IM injection site. Other: Rash, pruritus, urticaria, erythema, petechiae, exfoliative dermatitis, flushing, diarrhoea, nausea, vomiting, abdominal cramps, mouth ulcer and altered taste, angioedema, bronchospasm.		
Pharmacokinetics	Elimination half-life is 1.7 hours.		
Significant interactions	 Aztreonam may <i>îlevels</i> or effect of the following drugs (or <i>îside-effects</i>): acenocoumarol (monitor INR), warfarin (monitor INR). 		
Action in case of overdose	No reported cases of overdosage. Stop administration and give supportive therapy as appropriate.		

Risk rating: GREEN	Score = 2 Lower-risk product: Risk-reduction strategies should be considered.	
Сонс		

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Bibliography

SPC Azactam for injection (accessed 1 October 2009).

Bemiparin sodium

2500 units/0.2 mL, 3500 units/0.2 mL pre-filled syringes 25 000 units/mL pre-filled syringes: 5000 units/0.2 mL, 7500 units/0.3 mL, 10 000 units/0.4 mL

- Bemiparin sodium is a low-molecular-weight heparin (LMWH).
- It is used in the treatment of venous thromboembolism (VTE) i.e. pulmonary embolism (PE) and deep vein thrombosis (DVT).
- It is used for prophylaxis of VTE in surgical patients and to prevent thrombus formation in the extracorporeal circulation during haemodialysis.
- · Not all products are licensed for all indications.
- Doses are expressed in terms of international anti-Factor Xa activity units.

Pre-treatment checks

- Avoid in acute bacterial endocarditis, major bleeding or high risk of uncontrolled haemorrhage including recent haemorrhagic stroke.
- Avoid in patients with severe impairment of renal, hepatic and/or pancreatic functions.
- It is contraindicated in treatment dosage in patients undergoing locoregional anaesthesia in elective surgical procedures.
- Placement or removal of a spinal/epidural catheter should be delayed for 10–12 hours after administration of prophylactic doses, whereas patients receiving treatment doses require a 24hour delay. Subsequent doses should be given no sooner than 4 hours after catheter removal.
- · Caution with other drugs affecting haemostasis such as aspirin or clopidogrel.
- Use with extreme caution in patients with a history of heparin-induced thrombocytopenia (HIT).

Biochemical and other tests (not all are necessary in an emergency situation)

Anti-Factor Xa activity in patients with severe	LFTs
renal impairment	Platelet count
Bodyweight (in some indications)	Renal function: U, Cr, CrCl (or eGFR)
Electrolytes–serum K	

Dose

Prophylaxis

General surgery with moderate risk of VTE: 2500 units by SC injection 2 hours before or 6 hours after surgery. On subsequent days give 2500 units every 24 hours for 7–10 days.

Orthopaedic surgery with high risk of VTE: 3500 units by SC injection 2 hours before or 6 hours after surgery. On subsequent days give 3500 units every 24 hours for 7–10 days.

Prevention of extracorporeal thrombus formation during haemodialysis: for haemodialysis of ≤ 4 hours duration, in patients not at risk of bleeding give 2500 units (weight <60 kg) or 3500 units (weight >60 kg) introduced into the arterial line at the start of the dialysis session.

Treatment

Treatment of VTE: give by SC injection once daily based on bodyweight as indicated in Table B1. For patients >100 kg dose is calculated on the basis of 115 units/kg and two syringes used to administer the dose. Treat for at least 5 days and until INR > 2.
 Table B1
 Treatment doses of bemiparin for VTE

	Bodyweight			
	< 50 kg	5070 kg	70-100 kg	>100 kg
Syringe volume	0.2 mL	0.3 mL	0.4 mL	115 units/kg -
Syringe dose	5000 units	7500 units	10 000 units	to provide dose

Dose in renal impairment: adjusted according to creatinine clearance:¹

- CrCl >20-50 mL/minute: dose as in normal renal function.
- CrCl 10-20 mL/minute: dose as in normal renal function for prophylaxis only.
- CrCl <10 mL/minute: dose as in normal renal function for prophylaxis only.

Dose in hepatic impairment: the manufacturer advises avoidance in severe hepatic impairment.

Subcutaneous injection

Preparation and administration

- 1. Select the correct pre-filled syringe. Pre-filled syringes are ready for immediate use; do not expel the air bubble.
- 2. The patient should be seated or lying down.
- 3. Pinch up a skin fold on the abdominal wall between the thumb and forefinger and hold throughout the injection.
- 4. Give by deep SC injection into the thick part of the skin fold at right angles to the skin. Do not rub the injection site after administration. Alternate doses between the right and left sides.

Arterial line injection (haemodialysis circuits)

- 1. Select the correct pre-filled syringe and expel the air bubble.
- 2. The solution should be clear and colourless to slightly yellowish. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give over 5 seconds via a port into the arterial limb of the haemodialysis circuit.

Technical information	
Incompatible with	Not relevant
Compatible with	Flush: NaCl 0.9% Solutions: Not relevant Y-site: Not relevant
pH ²	5-7.5
Sodium content	Negligible
Storage	Store below 25°C in original packaging.

80 | Bemiparin sodium

Monitoring					
Measure	Frequency		Rationale		
Platelet count	Twice a week		 Thrombocytopenia can occur from day 5 to day 21 of therapy. A 50%↓ in platelets is indicative of HIT and therapy should be switched to a non-heparin-derived agent. 		
Serum K	After 7	' days	 Heparins inhibit the secretion of aldosterone and so may cause <i>†</i>K. Monitor in all patients with risk factors, particularly if therapy >7 days. 		
Signs of bleeding	Throug therap	jhout Y	• There is a higher risk of bleeding with prophylactic doses in low bodyweight: women (<45 kg); men (<57 kg).		
Anti-Xa activity	Periodically - see rationale		 Not required routinely but may be considered in patients at \risk of bleeding or actively bleeding. 		
Additional	infor	mation			
Common and s undesirable effe	erious ects	 Injection-related: Local: Pain, haematoma and mild local irritation may follow the SC injection of bemiparin. Exceptional cases of skin necrosis, usually preceded by purpura or erythematous plaques - treatment must be discontinued. Other: Common: Bleeding risk with organic lesions, invasive procedures; risk of major haemorrhage. Mild, transient, asymptomatic thrombocytopenia during the first days of therapy. Transient [liver transaminases. Rare: Immunoallergic thrombocytopenia with or without thrombosis. Significant ↑K in patients with diabetes or chronic renal failure. 			
Pharmacokineti	cs	Rapidly absorbed after SC injection (peak activity 2-3 hours) with elimination half-life of 5-6 hours. Elimination is prolonged in renal impairment and severe hepatic dysfunction.			
Significant interactions		 The following may ↑risk of bleeding with bemiparin: aspirin, diclofenac IV (avoid combination), ketorolac (avoid combination). Glyceryl trinitrate infusion may ↓bemiparin levels or effect. 			
Action in case of overdose	of	Symptoms to watch for: Bleeding. Antidote: Protamine sulfate may be used to ↓bleeding risk if clinically required. See Protamine sulfate monograph.			
Counselling		Report any bleeding or bruising, and any injection-site effects.			
Risk rating: GR	EEN	Score = 1 Lower-risk product. Risk-reduction strategies should be considered.			

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Benzatropine mesilate (benztropine mesylate)

1 mg/mL solution in 2-mL ampoules

- · Benzatropine mesilate is an antimuscarinic drug.
- It is used parenterally to treat acute dystonic reactions and extra pyramidal symptoms caused by drugs.

Pre-treatment checks

- Do not use to treat tardive dyskinesia as it is ineffective.
- Do not use in closed-angle glaucoma.
- Benzatropine may cause anhidrosis use with caution in hot weather especially when given with
 other atropine-like drugs to the chronically ill, in alcoholism, those who have CNS disease and
 those who do manual labour in a hot environment.

Biochemical and other tests

None required.

Dose

Onset of action is similar for the IM and IV routes and therefore IV administration is rarely required.

Standard dose: 1-2 mg by IM or IV injection. Repeat if symptoms reappear. Maximum daily dose: 6 mg.

Intramuscular injection (preferred route)

Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

Intravenous injection

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection.

82 | Benzatropine mesilate

Technical information	
Incompatible with	Haloperidol
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9% Y-site: Fluconazole, metoclopramide
рН	5-8
Sodium content	Negligible
Storage	Store below 25°C in original packaging. Do not freeze.
Monitoring	

Measure	Frequency	Rationale
Reduction of extrapyramidal movements, rigidity, tremor, gait disturbances.	Post administration	• To ensure that treatment is effective.
Pulse		• May cause ↑pulse.

Additional information

Common and serious undesirable effects	Common: $\ensuremath{\uparrow} \ensuremath{Pulse}$, constipation, nausea, dry mouth, blurred vision, urinary retention.
Pharmacokinetics	Given by the IM route, onset of effect occurs within minutes. There is very little information available about its elimination half-life.
Significant interactions	No significant interactions are known.
Action in case of overdose	Symptoms to watch for: Agitation, restlessness and severe sleeplessness lasting 24 hours or more. Visual and auditory hallucinations have been reported. <i>îPulse</i> has also been reported. <i>Antidote:</i> Active measures such as the use of cholinergic agents or haemodialysis are unlikely to be of clinical value. If convulsions do occur they should be controlled by injections of diazepam.

Risk rating: GREEN	Score = 1 Lower-risk product: Risk-reduction strategies should be considered.		

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Benzylpenicillin (penicillin G)

600-mg, 1.2-g dry powder vials

- · Benzylpenicillin sodium is a penicillin.
- It is bactericidal against Gram-positive bacteria, Gram-negative cocci, some other Gram-negative bacteria, spirochaetes, and actinomycetes.
- · Doses below are expressed in terms of the sodium salt.
- In some countries the dose is expressed as units: Benzylpenicillin sodium 600 mg ≈ 1 000 000 units (1 mega unit) of benzylpenicillin

Pre-treatment checks

• Do not give if there is known hypersensitivity to penicillins and use with caution if sensitive to other beta-lactam antibiotics.

Biochemical and other tests

Electrolytes: serum Na, K FBC Renal function: U, Cr, CrCl (or eGFR)

Dose

Standard dose: 600 mg-1.2 g by IM or IV injection or IV infusion every 6 hours, increased if necessary in more serious infections.

Endocarditis (in combination with another antibacterial if indicated): 1.2 g by IV injection or infusion every 4 hours, increased if necessary (e.g. in enterococcal endocarditis or monotherapy) to 2.4 g every 4 hours.

Anthrax (in combination with other antibacterials): 2.4 g by IV injection or infusion every 4 hours. **Intrapartum prophylaxis against group B streptococcal infection:** initially 3 g by IV injection or infusion then 1.5 g every 4 hours until delivery.

Meningococcal disease: 2.4 g by IV injection or infusion every 4 hours.

Dose in renal impairment: adjusted according to creatinine clearance:¹

- CrCl >20-50 mL/minute: dose as in normal renal function.
- CrCl 10-20 mL/minute: 600 mg-2.4 g every 6 hours depending on the severity of the infection.
- CrCl <10 mL/minute: 600 mg-1.2 g every 6 hours depending on the severity of the infection.

Intravenous injection

Preparation and administration

See Special handling below.

 Reconstitute each 600-mg vial with 5 mL WFI or NaCl 0.9% (use 10 mL for each 1.2-g vial). If planning to administer part of a 600-mg vial, use 5.6 mL WFI or NaCl 0.9%, which then gives a solution containing 100 mg/mL.

84 | Benzylpenicillin

- 2. Withdraw the required dose.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over about 5 minutes (maximum rate 300 mg/minute).

Intermittent intravenous infusion

Preparation and administration

See Special handling below.

- 1. Reconstitute each 600-mg vial with 5 mL WFI or NaCl 0.9% (use 10 mL for each 1.2-g vial). If planning to administer part of a 600-mg vial use 5.6 mL WFI or NaCl 0.9% which then gives a solution containing 100 mg/mL.
- Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually 100 mL NaCl 0.9%).
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 30-60 minutes.

Intramuscular injection (maximum dose 1.2g)

Preparation and administration

See Special handling below.

- 1. Dissolve the contents of a 600-mg vial in 1.6 mL of WFI (use 3.2 mL for a 1.2-g vial) to give a solution containing 300 mg/mL.
- 2. Withdraw the required dose.
- 3. Give by deep IM injection. Rotate injection sites for subsequent injections.

Technical information		
Incompatible with	Amphotericin, flucloxacillin, methylprednisolone sodium succinate, potassium chloride.	
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5% (but less stable) Y-site: Calcium gluconate, chloramphenicol sodium succinate, clarithromycin, clindamycin phosphate, erythromycin lactobionate, furosemide, hydrocortisone sodium succinate, ranitidine, verapamil	
рН	5.5-7.5	
Sodium content	1.7 mmol/600 mg; 3.4 mmol/1.2 g	
Storage	Store below 25°C in original packaging.	
Displacement value	0.4 mL/600 mg	

Technical information (continued)		
Special handling	After contact with skin, wash immediately with water. If it contacts the eyes, rinse immediately with plenty of water; seek medical advice if discomfort persists.	
Stability after preparation	Use reconstituted vials and prepared infusions immediately.	

Monitoring

Measure	Frequency	Rationale
Renal function, U&Es	Periodically if used for longer than 5 days	 The high Na content can cause ↓K (a K-sparing diuretic may help protect against this) and ↑Na (caution in renal failure and/or heart failure: use a non-Na-containing infusion fluid if indicated). Changes in renal function may require a dose adjustment.
FBC		 ↑risk of neutropenia when given over long periods. Warning signs include fever, rash, and eosinophilia. WCC: For signs of the infection resolving.
Signs of supra- infection or superinfection	Throughout treatment	 May result in the overgrowth of non-susceptible organisms - appropriate therapy should be commenced; treatment may need to be interrupted.
Signs of hypersensitivity		 Observe for 30 minutes after administration; if an allergic reaction occurs withdraw the drug and give appropriate treatment. Rashes, fever, serum sickness all commonly occur. Antihistamines are the treatment of choice.
Development of diarrhoea	Throughout and up to 2 months after treatment	 Development of severe, persistent diarrhoea may be suggestive of <i>Clostridium difficile</i>-associated diarrhoea and colitis (pseudomembranous colitis). Discontinue drug and treat. Do not use drugs that inhibit peristalsis.
Additional information		
Common and serious undesirable effects	Immediate: Anaphylaxis and other hypersensitivity reactions have been reported.	

	Other: Urticaria, fever, joint pains, rashes, angioedema, anaphylaxis, serum sickness-like reaction. Patients treated for syphilis or neurosyphilis may develop a Jarisch-Herxheimer reaction (occurs 2-12 hours after initiation of therapy - headache, fever, chills, sweating, sore throat, myalgia, arthralgia, malaise, ↑pulse and ↑BP followed by a ↓BP. Usually subsides within 12-24 hours. Corticosteroids may ↓incidence and severity).
Pharmacokinetics	Elimination half-life is 20-50 minutes.
Significant interactions	No significant interactions.

86 | Benzylpenicillin | Betamethasone

Additional information (continued)		
Action in case of overdose	Symptoms to watch for: Large doses have been associated with seizures. Antidote: None, but haemodialysis may be effective. Stop administration and give supportive therapy as appropriate.	
Counselling	Women taking the combined contraceptive pill should be should be advised to take additional precautions during and for 7 days after the course.	
Risk rating: GREEN	Score = 2	

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Bibliography

SPC Crystapen injection (accessed 2/03/09).

Betamethasone

4 mg/mL solution in 1-mL ampoules

- · Betamethasone sodium phosphate is a corticosteroid with mainly glucocorticoid activity.
- It is used in the treatment of conditions for which systemic corticosteroid therapy is indicated (except adrenal-deficiency states). Its virtual lack of mineralocorticoid properties makes it particularly suitable for treating conditions in which water retention would be a disadvantage.
- · It is also used by local injection in soft-tissue injury such as tennis elbow, tenosynovitis and bursitis.
- Doses are usually expressed in terms of the base: Betamethasone $1 \text{ mg} \cong 1.3 \text{ mg}$ betamethasone sodium phosphate.

Pre-treatment checks

- Avoid where systemic infection is present (unless specific therapy given).
- · Avoid live virus vaccines in those receiving immunosuppressive doses.
- May activate or exacerbate amoebiasis or strongyloidiasis (exclude before initiating a corticosteroid in those at risk or with suggestive symptoms). Fungal or viral ocular infections may also be exacerbated.
- Caution in patients predisposed to psychiatric reactions, including those who have previously suffered corticosteroid-induced psychosis, or who have a personal or family history of psychiatric disorders.

• Do not use in the treatment of cerebral oedema associated with acute head injury or cerebrovascular accident, as it is unlikely to be of benefit and may even be harmful.

Biochemical and other tests (not all are necessary in an emergency situation)

Electrolytes: serum Na, K, Ca LFTs

Dose

Standard dose: 4–20 mg by IV injection repeated 3–4 times in 24 hours, or as required, depending upon the condition being treated and the patient's response. It may also be given by IM injection and IV infusion.

Injection into soft tissue: 4–8 mg repeated on 2–3 occasions depending upon the patient's response.

Dose in hepatic impairment: as betamethasone is metabolised in the liver, dosage adjustments may be necessary.

Intravenous injection (preferred route)

Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 30-60 seconds.

Intramuscular injection (less rapid response)

Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by deep IM injection.

Intermittent intravenous infusion

Preparation and administration

- 1. Withdraw the required dose.
- 2. Add to a suitable volume of compatible infusion fluid (usually 100 mL NaCl 0.9%).
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 15-30 minutes.

Technical information		
Incompatible with	No information	
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5% Y-site: No information	
рН	8-9	
Sodium content	Negligible	
Excipients	Contains sulfites (may cause allergic reactions).	

88 | Betamethasone

Technical information (continued)		
Storage	Store below 30°C in original packaging.	
Stability after preparation	Use prepared infusions immediately.	
Monitoring		
Measure	Frequency	Rationale
Serum Na, K, Ca	Throughout treatment	• May cause fluid and electrolyte disturbances.
Withdrawal symptoms and signs	During withdrawal and after stopping treatment	 During prolonged therapy with corticosteroids, adrenal atrophy develops and can persist for years after stopping. Abrupt withdrawal after a prolonged period can lead to acute adrenal insufficiency, JBP or death. The CSM has recommended that gradual withdrawal of systemic corticosteroids should be considered in patients whose disease is unlikely to relapse. Full details can be found in the BNF.
Signs of infection	During treatment	Prolonged courses <i>fsusceptibility to infections and</i> severity of infections. Serious infections may reach an advanced stage before being recognised.
Signs of chickenpox		 Unless they have had chickenpox, patients receiving corticosteroids for purposes other than replacement should be regarded as being at risk of severe chickenpox. Confirmed chickenpox requires urgent treatment; corticosteroids should not be stopped and dosage may need to be increased.
Exposure to measles		 Patients should be advised to take particular care to avoid exposure to measles and to seek immediate medical advice if exposure occurs. Prophylaxis with IM normal immunoglobulin may be needed.

Additional information

Common and serious	Immediate: Anaphylaxis and other hypersensitivity reactions have been reported.
undesirable effects	Undesirable effects that may result from short-term use (minimise by using the lowest effective dose for the shortest time): ↑BP, Na and water retention, ↓K, ↓Ca, ↑blood glucose, peptic ulceration and perforation, psychiatric reactions, ↑susceptibility to infection, muscle weakness, tendon rupture, insomnia, ↑intracranial pressure, ↓seizure threshold, impaired healing. For undesirable effects resulting from long-term corticosteroid use, refer to the BNF.
Pharmacokinetics	Elimination half-life is 5.6 hours.

Additional information (continued)		
Significant interactions	 The following may ↓corticosteroid levels or effect: barbiturates, carbamazepine, phenytoin, primidone, rifabutin, rifampicin. Corticosteroids may ↑levels or effect of the following drugs (or ↑side-effects): aldesleukin (avoid combination), amphotericin (risk of ↑K), anticoagulants (monitor INR), methotrexate (↑risk of blood dyscrasias). Corticosteroids may ↓levels or effect of vaccines (↓immunological response, ↑risk of infection with live vaccines). 	
Action in case of overdose	Give supportive therapy as appropriate. Following chronic overdose the possibility of adrenal suppression should be considered.	
Counselling	Patients on long-term corticosteroid treatment should read and carry a Steroid Treatment Card.	

Risk rating: GREEN		Score = 1 Lower-risk product: Risk-reduction strategies should be considered.		
This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.				

Bibliography

SPC Betnesol injection (accessed 1 October 2009).

Bivalirudin

250-mg dry powder vials

- Bivalirudin, an analogue of the peptide hirudin, is a direct thrombin inhibitor with actions similar to lepirudin.
- It is used as an anticoagulant in patients undergoing PCI, including those with, or at risk of, HIT. It is also licensed for use in the acute coronary syndromes (ACS): unstable angina and NSTEMI.

Pre-treatment checks

- Avoid in severe ↑BP; sub-acute bacterial endocarditis; active bleeding; bleeding disorders.
- Caution with previous exposure to lepirudin (theoretical risk from lepirudin antibodies), brachytherapy procedures, and concomitant use of drugs that ↑risk of bleeding.
- Bivalirudin may be commenced 30 minutes after discontinuation of an unfractionated heparin IV infusion, or 8 hours after discontinuation of SC LMWH.
Biochemical and other tests (not all are necessary in an emergency situation)

ACT Blood pressure Bodyweight FBC Renal function: U, Cr, CrCl (or eGFR)

Dose

Patients undergoing PCI: 0.75 mg/kg by IV injection followed immediately by 1.75 mg/kg/hour by IV infusion for at least the duration of the procedure. This infusion may be continued for up to 4 hours post-PCI if necessary. After the 1.75 mg/kg/hour infusion has a finished, a reduced infusion of 0.25 mg/kg/hour may be continued for 4–12 hours as clinically necessary.

Treatment of ACS: 0.1 mg/kg by IV injection followed by 0.25 mg/kg/hour by IV infusion. Patients who are to be medically managed may continue the infusion for up to 72 hours.

ACS patients proceeding to PCI: an additional 0.5 mg/kg by IV injection is given before the procedure and the infusion increased as per PCI patients above.

ACS patients who proceed to coronary artery bypass graft (CABG) surgery off pump: the infusion is continued until the time of surgery. An additional 0.5 mg/kg by IV injection is given just prior to surgery followed by 1.75 mg/kg/hour by IV infusion for the duration of the surgery.

ACS patients who proceed to CABG surgery on pump: the infusion is continued until 1 hour prior to surgery then stopped and the patient treated with unfractionated heparin.

Dose in renal impairment: adjusted according to creatinine clearance:

- CrCl 30–59 mL/minute: loading dose remains unchanged but the IV infusion for patients undergoing PCI (whether being treated for ACS or not) should be reduced to 1.4 mg/kg/hour.
- CrCl <30 mL/minute: do not use.

Intravenous injection

Preparation and administration

- 1. Reconstitute each 250-mg vial with 5 mL WFI. Swirl gently until completely dissolved to give a solution containing 50 mg/mL.
- Withdraw 5 mL from the vial and further dilute to a final volume of 50 mL with Gluc 5% or NaCl 0.9% to give a solution containing 5 mg/mL. Mix well.
- The solution should be a clear to slightly opalescent, colourless to slightly yellow solution. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Withdraw the required dose (retain the remainder of the solution for IV infusion).
- 5. Give as a rapid IV injection.

Continuous intravenous infusion via a syringe pump

- 1. For the initial IV infusion, use the remainder of the solution prepared for IV injection.
- When a further supply is needed, reconstitute each 250-mg vial with 5 mL WFI. Swirl gently until completely dissolved to give a solution containing 50 mg/mL.
- Withdraw 5 mL from the vial and make up to 50 mL in a syringe pump with Gluc 5% or NaCl 0.9%.
- 4. Cap the syringe and mix well to give a solution containing 5 mg/mL.
- 5. The solution should be a clear to slightly opalescent, colourless to slightly yellow solution. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 6. Give by IV infusion at a rate appropriate to the indication.

Technical inform	ation
Incompatible with	Alteplase, amiodarone, amphotericin, diazepam, dobutamine, prochlorperazine, reteplase, streptokinase, vancomycin.
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5% Y-site: Abciximab, alfentanil, amikacin, aminophylline, ampicillin, aztreonam, bumetanide, calcium gluconate, cefotaxime, ceftazidime, ceftriaxone, ciprofloxacin, clindamycin phosphate, co-trimoxazole, dexamethasone sodium phosphate, dopamine, eptifibatide, erythromycin lactobionate, esmolol, fentanyl, fluconazole, furosemide, gentamicin, glyceryl trinitrate, hydrocortisone sodium succinate, labetalol, magnesium sulfate, methylprednisolone sodium succinate, metoclopramide, metronidazole, midazolam, noradrenaline (norepinephrine), piperacillin with tazobactam, ranitidine, ticarcillin with clavulanate, tobramycin, verapamil
рН	5-6
Sodium content	Negligible
Storage	Store below 25°C in original packaging.
Displacement value	Negligible
Stability after preparation	 From a microbiological point of view should be used immediately, however: Reconstituted vials may be stored at 2-8°C for 24 hours. Prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours.

Monitoring

Measure	Frequency	Rationale
ACT	Initially 5 minutes after loading dose (see also rationale)	 If the 5-minute ACT is <225 seconds, a second bolus dose of 0.3 mg/kg should be given and rechecked after a further 5 minutes. Once the ACT value is >225 seconds, no further monitoring is required provided the IV infusion is properly given.
Renal function	Periodically	 Changes in renal function may require an adjustment in infusion rate, but check ACT first.
FBC and Blood pressure		 Unexplained the aematocrit, Hb or BP may indicate haemorrhage. Treatment should be stopped if bleeding is observed or suspected. Consider testing stool for occult blood.

Additional information		
Common and serious undesirable effects	<i>Immediate:</i> Anaphylaxis and other hypersensitivity reactions have been reported rarely. <i>Other:</i> Minor bleeding at any site, major haemorrhage at any site (including reports with fatal outcome), bruising.	
Pharmacokinetics	Elimination half-life is 35-40 minutes.	
Significant interactions	 The following may <i>î</i>bivalirudin levels or effect (or <i>î</i>side-effects): thrombolytics, coumarin anticoagulants, antiplatelet drugs. 	
Action in case of overdose	No known antidote. Stop administration and give supportive therapy as appropriate. Monitor for signs of bleeding.	

Risk rating: AMBER	Score = 5 Moderate-risk product: Risk-reduction strategies are recommended.

Bumetanide

500 micrograms/mL solution in 4-mL ampoules

- Bumetanide is a loop diuretic with properties similar to those of furosemide.
- It may be given parenterally when the oral route is unavailable or ineffective in oedematous conditions, e.g. acute pulmonary oedema, acute and chronic renal failure.

Pre-treatment checks

- Do not use in hypovolaemia, dehydration, severe ↓K, severe ↓Na; comatose or pre-comatose states associated with liver cirrhosis; renal failure due to nephrotoxic or hepatotoxic drugs, anuria.
- Caution in

 BP; prostatic enlargement; impaired micturition; gout; diabetes; hepato-renal syndrome; hepatic impairment; renal impairment.
- Fluid balance and electrolytes should be carefully controlled and, in particular in patients with shock, measures should be taken to correct BP and circulating blood volume before commencing treatment.

Biochemical and other tests

Blood glucose Blood pressure Electrolytes: serum Na, K, Mg LFTs Renal function: U, Cr, CrCl (or eGFR)

Dose

Pulmonary oedema: initially 1–2 mg (or 500 micrograms in elderly patients) by IV injection, repeated 20 minutes later if necessary. Alternatively, give 1 mg by IM injection (or 500 micrograms in elderly patients) and adjust dose according to response.

Persistent oedematous states: 2–5 mg by IV infusion. In elderly patients, 500 micrograms daily may be sufficient.

Intravenous injection (for doses up to 2 mg)

Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 1-2 minutes.

Intermittent intravenous infusion (for doses above 2 mg)

Preparation and administration

- 1. Withdraw the required dose and add to a suitable volume of NaCl 0.9% or Gluc 5% (the manufacturer advises 500 mL; solutions containing up to 1 mg/10 mL have been used).
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 30-60 minutes. Protect from direct sunlight.

Intramuscular injection

- 1. Withdraw the required dose.
- 2. Give by IM injection.

Technical information		
Incompatible with	Dobutamine, midazolam, milrinone.	
Compatible with	Flush: NaCl 0.9% Solutions: Gluc 5%, NaCl 0.9%, Gluc-NaCl, Hartmann's Y-site: Aztreonam, bivalirudin, cisatracurium, clarithromycin, granisetron, piperacillin with tazobactam, propofol, remifentanil	
рН	7	
Sodium content	Negligible	
Storage	Store below 25°C in original packaging.	
Stability after preparation	From a microbiological point of view, should be used immediately; however, may be stored at 2-8°C and infused (at room temperature) within 24 hours. Protect from direct sunlight. Discard if discoloured, cloudy or evidence of precipitation.	

94 | Bumetanide

Monitoring			
Measure	Frequency	Rationale	
Urinary output and relief of symptoms	Throughout treatment	Response to therapy.	
Fluid balance, serum electrolytes, and bicarbonate	Periodically	 Fluid balance should be carefully controlled. Electrolyte disturbances and metabolic alkalosis may occur. Replace if necessary. Disturbances may require temporary discontinuation of therapy. ↓K may precipitate coma (use a K-sparing diuretic to prevent this). ↑Risk of ↓Mg in alcoholic cirrhosis. 	
Renal function		 Changes in renal function may require a different dose or rate of infusion. A marked <i>jblood</i> urea or the development of oliguria or anuria indicates severe progression of renal disease and treatment should be stopped. 	
Blood pressure		 Potential for LBP and circulatory collapse resulting from rapid mobilisation of oedema fluid. 	
Blood glucose		 Reduced serum potassium may blunt response to insulin in patients with diabetes mellitus. 	
Additional infor	mation		
Common and serious undesirable effects	Injection/infusion-related: Too rapid administration: Tinnitus and deafness. Other: ↓Ca, ↓K, ↓Na, ↑uric acid levels, ↑blood glucose, ↓BP, dehydration, blood dyscrasias.		
Pharmacokinetics	Plasma elimination half-	Plasma elimination half-life is about 1-2 hours.	
Significant interactions	 Bumetanide may ↑risk of ototoxicity with the following drugs: aminoglycosides, polymyxins, vancomycin. ↓K due to bumetanide may ↑risk of cardiotoxicity with the following drugs: amisulpride, atomoxetine, cardiac glycosides, disopyramide, flecainide, pimozide, sertindole, sotalol. Bumetanide may cause ↓BP with the following drugs: ACE inhibitors, alpha blockers, ATII receptor antagonists Bumetanide may ↑levels (or ↑side-effects) of lithium (avoid combination or monitor levels). Bumetanide may ↓effect of lidocaine (↓K antagonises action). 		
Action in case of overdose	Treat with fluid replacer	ment and electrolytes as necessary.	
Counselling	Inform patient to report muscle pains/cramps and hearing disturbance.		

Bibliography

SPC Bumetanide injection 0.5 mg/mL, solution for injection, Leo Laboratories Ltd (accessed 15 April 2010).

Buprenorphine

300 micrograms/mL solution in 1-mL ampoules

- Buprenorphine hydrochloride is a strong centrally acting opioid analgesic that, at higher doses, also has an opioid antagonist effect (it may antagonise itself and other opioids). It has a lower risk of dependence than that of a pure opiate agonist such as morphine.
- It is used for the treatment of moderate to severe pain.
- Following IM injection analgesia is seen after 10 minutes and lasts for up to 6 hours (onset is quicker after IV injection).
- Doses are expressed in terms of the base: Buprenorphine 100 micrograms ≅108 micrograms buprenorphine hydrochloride.

Pre-treatment checks

- Do not use in acute respiratory depression, where there is a risk of paralytic ileus, in ↑intracranial pressure and in head injury, in comatose patients and phaeochromocytoma.
- Caution in JBP, shock, convulsive disorders, supraventricular tachycardias, atrial flutter, chronic
 obstructive pulmonary disease and acute asthma attack, obstructive or inflammatory bowel diseases, biliary tract diseases, alcoholism, prostatic hyperplasia, myasthenia gravis, hypothyroidism
 (reduce dose), adrenocortical insufficiency (reduce dose).

Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure and pulse LFTs Pain score Renal function: U, Cr, CrCl (or eGFR) Respiratory rate

Dose

Pain: 300–600 micrograms every 6–8 hours as required by IM or IV injection. High-risk patients (i.e. risk of respiratory/CNS depression): use half the usual adult dose. Dose in renal or hepatic impairment: reduce dose or avoid.

Intramuscular injection

Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by deep IM injection.
- 3. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving initial dose, especially elderly patients or those of low bodyweight.

Intravenous injection

Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over at least 2 minutes.
- 4. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving initial dose, especially elderly patients or those of low bodyweight.

Technical information		
Incompatible with	Diazepam, flucloxacillin, furosemide, lorazepam.	
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, Gluc-NaCl, Hartmann's Y-site: Aztreonam, cisatracurium, granisetron, midazolam, piperacillin with tazobactam, propofol, remifentanil	
рН	3.5-5.5	
Sodium content	Nil	
Storage	Store below 25°C in original packaging. Do not freeze. Controlled Drug.	

Monitoring

Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving initial dose, especially elderly patients of those of low bodyweight.

Measure	Frequency	Rationale
Pain score	At regular intervals	• To ensure therapeutic response.
Blood pressure, pulse and respiratory rate		• ↓BP, ↓pulse, ↑pulse, palpitations and respiratory depression with ↓ oxygen saturation can occur.
Sedation		Can cause sedation and CNS depression.

Additional information		
Common and serious undesirable effects	Immediate: Serious hypersensitivity reactions have been reported rarely. Other: Nausea and vomiting (particularly initially), constipation, dry mouth, urticaria, pruritus, biliary spasm, ↑ or ↓pulse, hallucinations, euphoria, drowsiness At higher dose: ↑ or ↓BP, sedation, respiratory depression, muscle rigidity	
Pharmacokinetics	Elimination half-life following IV administration is an average of 2.2 hours. Plasma level/analgesia relationship is highly variable.	
Significant interactions	 The following may <i>î</i>buprenorphine levels or effect (or <i>î</i>side-effects): antihistamines-sedating (<i>î</i>sedation), ketoconazole (<i>i</i>dose), MAOIs (avoid combination and for 2 weeks after stopping MAOI), moclobemide. Buprenorphine may <i>î</i>levels or effect (or <i>î</i>side-effects) of sodium oxybate (avoid combination). 	
Action in case of overdose	Symptoms to watch for: †Sedation, respiratory depression. Antidote: Naloxone (see the Naloxone monograph) but may only partially reverse toxicity. Stop administration and give supportive therapy as appropriate.	
Counselling	May cause drowsiness and dizziness, which may affect the ability to perform skilled tasks; if affected, do not drive or operate machinery, avoid alcoholic drink (the effects of alcohol are enhanced). Drink plenty of fluids to help avoid constipation.	

Risk rating: GREEN	Score = 2 Lower-risk prod	duct: Risk-re	eduction strategies should be considered.
This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.			

Bibliography

SPC Temgesic injection 1 ml (accessed 29 June 2008).

Buserelin

1 mg/mL solution in 5.5-mL multidose vials

- · Buserelin acetate is an analogue of gonadorelin (gonadotrophin-releasing hormone).
- In men it is used for the suppression of testosterone in the treatment of prostate cancer (Suprefact).
- In women it is used SC as an adjunct to ovulation induction with gonadotrophins in the treatment of infertility (Suprecur). It is also used intranasally in the treatment of endometriosis.
- Doses are expressed in terms of the base: Buserelin 1 mg ≡ 1.05 mg buserelin acetate.

Pre-treatment checks

- Do not give if there is known hypersensitivity to LHRH or buserelin.
- Contraindicated if tumour is found to be insensitive to hormone manipulation, and in cases of undiagnosed vaginal bleeding.
- Do not use in pregnancy.
- Caution in osteoporosis or those at risk (i.e. chronic alcohol and/or tobacco use, strong family
 history of osteoporosis or long-term use of drugs that can reduce bone mass e.g. anticonvulsants or
 corticosteroids).
- Screen for depression in men.

Biochemical and other tests

 Baseline lipid profile
 LFTs

 Blood pressure
 Pregnancy test if appropriate

 FBC
 FBC

Dose

Prostate cancer: 500 micrograms by SC injection every 8 hours for 7 days. On the eighth day the patient is changed to maintenance therapy by the intranasal route. An anti-androgen agent may be given for 5 days before until 3–4 weeks after commencement to \downarrow risk of disease flare, e.g. cyproterone acetate 100 mg three times daily.

Assisted reproduction: 200–500 micrograms by SC injection once daily is administered to downregulate the pituitary gland. Serum estradiol levels should decline to levels similar to those in the early follicular phase in 7–21 days. Gonadotrophin is then administered following the protocol of the individual clinic.

Subcutaneous injection

Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by SC injection.

Technical information	
Incompatible with	Not relevant
Compatible with	Not relevant
рН	Not relevant

(continued)

Buserelin 99

Technical information (continued)			
Sodium content	Negligible		
Excipients	Contains benzyl al	Contains benzyl alcohol.	
Storage	Store below 25°C Discard vials 10 do	in original packaging. Do not freeze. ays after opening.	
Monitoring			
Measure	Frequency	Rationale	
Blood glucose in diabetic patients	Regularly	• ↑Blood glucose levels can occur (↓glucose tolerance).	
Monitor for signs of OHSS in women	During treatment	 When combined with gonadotrophins there is a higher risk of OHSS than with gonadotrophins alone. The stimulation cycle should be monitored carefully to identify patients at risk of developing OHSS and HCG should be withheld if necessary. Symptoms include: abdominal pain, feeling of abdominal tension, ↑abdominal girth, occurrence of ovarian cysts, nausea, vomiting, massive enlargement of the ovaries, dyspnoea, diarrhoea, oliguria, haemoconcentration, hypercoagulability. 	
Serum testosterone in men	If indicated	 Consider measurement if the anticipated clinical or biochemical response in prostate cancer has not been achieved within 4 weeks (levels <20 nanograms/dL are considered equivalent to surgical castration).¹ 	
LFTs	Periodically	• Levels of serum Alk Phos and bilirubin may be raised.	
Blood lipid levels		• Lipid levels can be lowered and raised.	
FBC		• Thrombocytopenia and leucopenia sometimes occur.	
Blood pressure		• ↓BP or ↑BP can occur (rarely) and may require medical intervention or withdrawal of treatment.	
Symptoms of depression in men		• Emotional instability is a frequent side-effect.	

Additional information

Common and serious undesirable effects	Immediate: Rarely anaphylaxis and other hypersensitivity reactions. Injection/infusion-related: Local: Injection-site pain, reddening of the skin, itching. Other: ↓BMD, hot flushes, sweating, ↓libido, breast tenderness (infrequently). Women: Headaches, mood changes, depression, vaginal dryness, change in breast size.
Pharmacokinetics	Elimination half-life is 80 minutes.

(continued)

100 | Buserelin

Additional information (continued)		
Significant interactions	No significant interactions.	
Action in case of overdose	There is no specific antidote and treatment should be symptomatic.	
Counselling	Buserelin may impair the ability to concentrate and react, so caution is needed if operating a vehicle or machinery. Fertile women should use non-hormonal barrier methods of contraception during the entire treatment period.	
Risk rating: GREEN	Score = 1 Lower-risk product: Risk-reduction strategies should be considered.	

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Calcitonin (salmon)

50 units/mL solution in 1-mL ampoules; 100 units/mL solution in 1-mL ampoules; 200 units/mL solution in 2-mL vials

- Calcitonin (salmon) is a hormone acting mainly on bone to \(Ca levels and inhibit bone resorption.)
 It is prepared synthetically or by recombinant DNA technology.
- There is some confusion about terminology, but in practice the terms salcatonin, calcitonin (salmon), salmon calcitonin and calcitonin-salmon appear to be used for the same substance.
- Calcitonin (salmon) is licensed for use in the treatment of Paget's disease (of bone), in hypercalcaemia of malignancy and to prevent acute bone loss due to sudden immobilisation. It is also licensed for intranasal use in the treatment of postmenopausal osteoporosis.
- Doses are expressed in units: Calcitonin (salmon) 128 units \cong 20 micrograms of freeze-dried purified synthetic salmon calcitonin.

Pre-treatment checks

- Avoid in hypocalcaemia.
- If sensitivity to calcitonin is suspected, a skin test should be conducted prior to treatment.
- · Ensure that the patient is adequately hydrated before giving by IV infusion.

Biochemical and other tests

Electrolytes: serum Ca

Dose

Administer at bedtime, particularly at the start of therapy, to *incidence* of nausea or vomiting.

Hypercalcaemia of malignancy: initially 100 units by SC or IM injection every 6–8 hours, increasing to a maximum of 400 units every 6–8 hours after 1–2 days if necessary. In severe or emergency cases up to 10 units/kg may be given by IV infusion.

Paget's disease: doses range from 50 units three times a week to 100 units daily by SC or IM injection adjusted to patient's needs.

Prevention of acute bone loss: 100 units daily or 50 units twice daily by SC or IM injection. The dose may be reduced to 50 units daily at the start of remobilisation; maintain treatment until patient is fully mobile.

Subcutaneous injection

Preparation and administration

- 1. Remove from refrigerator and allow injection to reach room temperature.
- 2. Withdraw the required dose.
- 3. Give by SC injection.

Intramuscular injection

- 1. Remove from refrigerator and allow injection to reach room temperature.
- 2. Withdraw the required dose.
- 3. Give by IM injection.

Intravenous infusion

Preparation and administration

- 1. Withdraw the required dose and add to 500 mL NaCl 0.9% (glass or hard plastic containers should not be used).
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over at least 6 hours.

Technical information		
Incompatible with	Glass or hard plastic containers should not be used.	
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9% Y-site: No information	
рН	3.9-4.5	
Sodium content	Negligible	
Storage	Store in a refrigerator (2-8°C). <i>In use:</i> Multidose vials may be stored at room temperature for a maximum of 1 month from first use.	
Stability after preparation	Use prepared infusions immediately.	
Monitoring		

Measure	Frequency	Rationale
Serum Ca	Daily when treatment commences then periodically	 Monitoring of effectiveness in hypercalcaemia of malignancy.
Markers of bone remodelling, e.g. Alk Phos or urinary hydroxyproline or deoxypyridinoline	Periodically	• Monitoring of effectiveness in Paget's disease.

Additional information

Common and serious undesirable effects	Immediate: Allergic reactions including anaphylaxis and bronchospasm have been reported. Flushing of the face or upper body is not an allergic reaction but is commonly seen 10-20 minutes after administration. Injection/infusion-related: Local: Injection-site reactions. Other: Nausea, vomiting (may be given at bedtime to reduce incidence of nausea and vomiting), diarrhoea, abdominal pain, musculoskeletal pain, fatigue, dizziness, headache, taste disturbances.
Pharmacokinetics	Elimination half-life is 1-1.5 hours. Clearance is longer in end-stage renal impairment but the clinical significance of this is unknown.

Additional information (continued)		
Significant interactions	No significant interactions.	
Action in case of overdose	Symptoms of overdose include nausea and vomiting. Treatment should be symptomatic and supportive.

SPC Miacalcic (accessed 6 July 2010).

Calcitriol (1,25-dihydroxycholecalciferol)

1 microgram/mL solution in ampoules

- The term vitamin D is used for a range of closely related sterol compounds including alfacalcidol, calcitriol, colecalciferol and ergocalciferol. Vitamin D compounds possess the property of preventing or curing rickets.
- Calcitriol injection is indicated in the management of hypocalcaemia in patients undergoing dialysis for chronic renal failure. It has been shown to significantly reduce elevated parathyroid hormone (PTH) levels. Reduction of PTH has been shown to result in an improvement in renal osteodystrophy.

Pre-treatment checks

- Do not give to patients with hypercalcaemia, including hypercalcaemia of malignancy.
- For treatment to be effective, patients should be receiving an adequate daily intake of calcium (dietary or prescribed).

Biochemical and other tests

Electrolytes: serum Ca, PO₄ Liver function: Alk Phos Renal function: U, Cr

Dose

Hypocalcaemia in adult dialysis patients: initially 500 nanograms (\simeq 10 nanograms/kg) three times a week, increased if necessary in steps of 250–500 nanograms at intervals of 2–4 weeks; usual dose 0.5–3 micrograms 3 times a week.

Moderate to severe secondary hyperparathyroidism in adult dialysis patients: initially 0.5–4 micrograms 3 times a week, increased if necessary in steps of 250–500 nanograms at intervals of 2–4 weeks; maximum dose is 8 micrograms 3 times a week.

Intravenous injection

- 1. Withdraw the required dose into a plastic 1-mL tuberculin syringe.
- The solution should be a clear, colourless to yellow solution. Inspect visually for particulate matter or discoloration prior to administration.
- 3. Give by rapid IV injection or through the catheter at the end of dialysis.

Technical information			
Incompatible with	Do not infuse with th absorption onto PVC	Do not infuse with the dialysate during CAPD as there is significant absorption onto PVC bags and tubing.	
Compatible with	Flush: NaCl 0.9% Solutions: No infor Y-site: No informati	Flush: NaCl 0.9% Solutions: No information Y-site: No information	
рН	5.9-7	5.9-7	
Sodium content	Negligible	Negligible	
Storage	Store below 25°C in	Store below 25°C in original packaging but do not refrigerate.	
Monitoring			
Measure	Frequency	Rationale	
Hypersensitivity	During and after	Local or systemic allergic reactions, including	

reactions	administration	anaphylaxis have been reported rarely.
Serum Ca and PO ₄	Initially weekly until dose and plasma Ca and PO ₄ are stable, then monthly; also whenever nausea or vomiting occurs	 ↑Ca and ↑PO₄ can occur during treatment with pharmacological doses of compounds having vitamin D activity. Plasma PO₄ concentrations should be controlled to reduce the risk of ectopic calcification.
LFTs	Monthly	• A fall in serum Alk Phos levels often precedes the appearance of ↑Ca.
Ophthalmological examination	Periodically	• To check for ectopic calcification.
Signs/symptoms of toxicity		• E.g. persistent constipation or diarrhoea, constant headache, loss of appetite, mental changes.

Additional information		
Common and serious undesirable effects	Immediate: Rarely hypersensitivity reactions including anaphylaxis. Injection-related: Local: Redness at injection site. Other: ↑Ca (persistent constipation or diarrhoea, constant headache, vertigo, loss of appetite, polyuria, thirst, sweating).	
Pharmacokinetics	Elimination half-life is 5-8 hours. However, the metabolic effects of calcitriol continue long after the plasma level of the hormone has returned to baseline therefore plasma half-life is considered irrelevant.	
Significant interactions	No significant interactions.	
Action in case of overdose	Stop treatment if \uparrow Ca develops until plasma Ca levels return to normal (about 1 week). Restart treatment at a lower dose if appropriate. In severe \uparrow Ca give supportive therapy as appropriate.	
Counselling	Advise patients to report symptoms of ↑Ca: persistent constipation or diarrhoea, constant headache, vertigo, loss of appetite, polyuria, thirst, sweating.	

Risk rating: GREEN	Score = 1 Lower-risk product: Risk-reduction strategies should be considered.

Calcium chloride

10% solution in 10-mL pre-filled syringes; 13.4% solution in 10-mL ampoules

- Calcium is the most abundant mineral in the body. It is required for bone and tooth formation and is an essential electrolyte.
- Normal range for plasma total calcium ('corrected' if necessary): 2.1-2.6 mmol/L.
- Calcium chloride may be used parenterally in cardiac resuscitation if PEA is thought to be caused by ↑K or ↓Ca or in calcium channel blocker overdose.¹
- Calcium salts are used to treat severe acute ↓Ca or tetany and to stabilise the myocardium in severe
 ↑K. Calcium gluconate is generally preferred to calcium chloride in non-emergency situations
 because it is less irritant to veins.
- Calcium salts are also used (unlicensed) in the treatment of patients with significant clinical features of magnesium poisoning.

10% calcium chloride injection contains:

Ca²⁺ 680 micromol/mL (calcium 27.3 mg/mL).

13.4% calcium chloride injection contains:

Ca²⁺ 910 micromol/mL (calcium 36 mg/mL).

These preparations must not be confused with calcium gluconate injection, which has a markedly different Ca^{2+} content.

Pre-treatment checks

- · Do not give to patients receiving cardiac glycosides.
- · Do not use for hypocalcaemia caused by renal impairment.
- Do not use in conditions associated with hypercalcaemia and hypercalciuria (e.g. some forms of malignant disease).
- Caution in patients with impaired renal function, cardiac disease, sarcoidosis, respiratory acidosis or respiratory failure.
- · In cardiac resuscitation do not administer if the patient is in ventricular failure.

Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure	Electrolytes: serum Ca
ECG	Renal function: Cr, CrCl (or eGFR)

Dose

Calcium chloride must not be given IM or SC. Calcium chloride is more irritant than calcium gluconate when given IV and is generally reserved for use in emergency situations.

Cardiac resuscitation: initially 6.8 mmol (10 mL of 10% injection \equiv 7.5 mL of 13.4% injection) repeated as necessary. In cardiac arrest give by rapid IV injection, in the presence of spontaneous circulation give by slow IV injection.¹

Acute hypocalcaemia: see the Calcium gluconate monograph.

Hyperkalaemia as part of overall treatment regimen (K > **6.5 mmol/L or if ECG changes are present):** see the Calcium gluconate monograph.

Magnesium toxicity: it is essential to consult a poisons information service, e.g. Toxbase at www. toxbase.org (password or registration required), for full details of the management of magnesium toxicity.

Intravenous injection (cardiac resuscitation)

Preparation and administration

Very irritant: give into the largest accessible vein if possible.

- 1. Either assemble the pre-filled syringe in accordance with the manufacturer's instructions or withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection into a large vein at a rate appropriate to the patient's clinical condition.

Calcium folinate (calcium leucovorin)

3 mg/mL, 7.5 mg/mL, 10 mg/mL solution in ampoules or vials (various sizes)

- Calcium folinate is a derivative of tetrahydrofolic acid, the active form of folic acid.
- It is used as an antidote to folic acid antagonists such as methotrexate (commonly known as 'folinic acid rescue' or 'calcium leucovorin rescue') and as an adjunct to fluorouracil (FU) in the treatment of colorectal cancer.
- Doses are usually expressed in terms of folinic acid: Folinic acid 1 mg ≅1.08 mg anhydrous calcium folinate.

Pre-treatment checks

• Do not give if the patient is anaemic owing to vitamin B₁₂ deficiency.

Biochemical and other tests

FBC LFTs Renal function: U, Cr, CrCl (or eGFR) U&Es

Dose

Calcium folinate **must not** be administered intrathecally.

Consult specialist literature as regimens vary greatly depending on the indication.

Intravenous injection

Preparation and administration

- 1. In the UK vials do not require reconstitution; in the USA some products require reconstitution with WFI (volume varies with product).
- 2. Withdraw the required dose.
- 3. The solution should be clear and pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection at a maximum rate of 160 mg/minute (due to the Ca content of the solution).

Intermittent intravenous infusion

Preparation and administration

- 1. In the UK vials do not require reconstitution; in the USA some products require reconstitution with WFI or NaCl 0.9% (volume varies with product).
- Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually 100–250 mL NaCl 0.9%).
- 3. The solution should be clear and pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over (usually) 2 hours. Protect from light.

Intramuscular injection

Preparation and administration

- In the UK vials do not require reconstitution; in the USA some products require reconstitution with WFI or NaCl 0.9% (volume varies with product).
- 2. Withdraw the required dose.
- 3. Give by IM injection.

Technical information

Incompatible with	Sodium bicarbonate. Amphotericin, fluorouracil, foscarnet.
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5% Y-site: Aztreonam, fluconazole, furosemide, granisetron, linezolid, metoclopramide, piperacillin with tazobactam
рН	6.5-8.5
Electrolyte content	Sodium: Negligible Calcium: 0.2 mmol/100 mg
Storage	Store at 2-8°C in original packing.
Stability after preparation	From a microbiological point of view, should be used immediately; however, prepared infusions may be protected from light, stored at 2-8°C and infused (at room temperature) within 24 hours.

110 | Calcium folinate

Monitoring		
Measure	Frequency	Rationale
Serum Ca	Periodically	 Monitored if combined with FU. Supplementation should be provided if Ca levels are low.
Diarrhoea	During treatment	 A sign of GI toxicity when combined with FU. ↓Dose of FU until symptoms have fully disappeared.
Creatinine and methotrexate levels	At least daily in folinic acid rescue	• Dose of calcium folinate is dependent on these parameters in 'rescue'.
FBC	Weekly during first two courses of FU then once each cycle thereafter	• In combination with FU only.
U&Es, LFTs	Prior to each treatment for the first 3 cycles and prior to every other cycle thereafter	• In combination with FU only.
Additional infor	mation	

Common and serious undesirable effects	In combination with FU: vomiting and nausea, severe mucosal toxicity, diarrhoea with higher grades of toxicity leading to dehydration.	
Pharmacokinetics	Elimination half-life is about 6 hours.	
Significant interactions	No significant interactions.	
Action in case of overdose	There have been no reports of overdose with calcium folinate.	

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Calcium gluconate

10% solution in 10-mL ampoules

- Calcium is the most abundant mineral in the body. It is required for bone and tooth formation and is an essential electrolyte.
- Normal range for plasma total calcium ('corrected' if necessary): 2.1-2.6 mmol/L.
- Calcium gluconate injection is used to treat severe acute ↓Ca or tetany and to stabilise the myocardium in severe ↑K.
- Calcium gluconate injection is also used (unlicensed) in the treatment of patients with significant clinical features of magnesium poisoning.
- Calcium may be used parenterally in cardiac resuscitation (more usually in the form of calcium chloride pre-filled syringes) if PEA is thought to be caused by ↑K or ↓Ca or in calcium channel blocker overdose.
- Intra-arterial calcium gluconate followed by hepatic venous sampling has been used to diagnose insulinomas (unlicensed).
- Because of the risk of aluminium exposure, calcium gluconate injection packed in small-volume glass containers should not be used for repeated or prolonged treatment in children < 18 years or in patients with renal impairment. Calcium gluconate injection packed in plastic containers may be used.¹

10% calcium gluconate injection contains: Ca²⁺ 225 micromol/mL (calcium 8.4 mg/mL).

This preparation must not be confused with calcium chloride injections, which have a markedly different Ca^{2+} content.

Pre-treatment checks

- · Do not give to patients receiving cardiac glycosides.
- · Do not use for hypocalcaemia caused by renal impairment.
- Do not use in conditions associated with hypercalcaemia and hypercalciuria (e.g. some forms of malignant disease) and in severe renal impairment.
- Caution in patients with mild to moderate renal impairment, cardiac disease, sarcoidosis, respiratory acidosis or respiratory failure.

Biochemical and other tests (not all are necessary in an emergency situation)

Renal function: U, Cr, CrCl (or eGFR)	ECG
Electrolytes: serum Ca	Bodyweight (in certain indications)

Dose

Calcium salts are irritant and may cause tissue necrosis and sloughing if given IM or SC. Calcium chloride is more irritant than calcium gluconate when given IV although both may cause irritation and should be given with care to avoid extravasation.

Acute hypocalcaemia: 2.25 mmol (10 mL of 10% injection) by slow IV injection. In tetany this should be followed by 9 mmol (40 mL of 10% injection) in 500 mL NaCl 0.9% or Gluc 5% by IV infusion daily over 8–24 hours with frequent monitoring of serum Ca. Smaller volumes may be used in fluid restriction.

112 | Calcium gluconate

An alternative regimen is to give 22.5 mmol Ca (100 mL of 10% injection) in 1 L of NaCl 0.9% or Gluc 5% solution by IV infusion at an initial rate of 50 mL/hour. Adjust the rate of infusion according to 4–6 hourly plasma Ca measurements.

Hyperkalaemia as part of overall treatment regimen (K > **6.5 mmol/L or if ECG changes are present):** give 10 mL calcium gluconate 10% by IV injection to stabilise cardiac muscle. Repeat as necessary, dependent on ECG.

Cardiac resuscitation: calcium chloride injection is preferred (see the Calcium chloride monograph).

Magnesium toxicity: it is essential to consult a poisons information service, e.g. Toxbase at www. toxbase.org (password or registration required), for full details of the management of magnesium toxicity.

Intravenous injection

Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV injection (10 mL of 10% injection over a minimum of 3 minutes).

Intermittent or continuous intravenous infusion

Preparation and administration

- 1. Withdraw the required dose and add to a 500–1000 mL (see information above) NaCl 0.9% or Gluc 5%. Mix well.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 8–24 hours depending on the dosing regimen. Adjust dose and rate according to serum Ca.
- 4. Prepare a fresh infusion bag at least every 24 hours.

Technical information Incompatible with Bicarbonates, phosphates, tartrates and sulfates. Amphotericin, dobutamine. Compatible with Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, Gluc-NaCl, Hartmann's Y-site: No information pН 6-8.2 Sodium content Nil Osmolality (plasma osmolality Calcium gluconate 10% ≈ 680 mOsmol/L. $= 280-300 \text{ mOsmol/L})^2$ Store below 25°C in original packaging. Calcium levofolinate (calcium levoleucovorin)

10 mg/mL solution in 2.5-mL, 5-mL or 17.5-mL vials

- Calcium levofolinate is the levorotatory enantiomer of calcium folinate. It is used in a similar way but generally at half the doses recommended for the racemic form.
- It is used as an antidote to folic acid antagonists such as methotrexate (commonly known as 'folinic acid rescue' or 'calcium leucovorin rescue') and as an adjunct to fluorouracil (FU) in the treatment of colorectal cancer.
- Doses are usually expressed in terms of folinic acid: Folinic acid 1 mg ≡ 1.08 mg anhydrous calcium levofolinate.

Pre-treatment checks

• Do not give if anaemic due to vitamin B₁₂ deficiency.

Biochemical and other tests

Capreomycin

1-g (1 million units) dry powder vials

- · Capreomycin sulfate is a polypeptide complex of four microbiologically active components.
- It may be used as a second-line antimycobacterial in the treatment of tuberculosis as part of a multidrug regimen when resistance to primary drugs has developed.
- · Doses are expressed in terms of capreomycin base.

Pre-treatment checks

Use with caution in patients with auditory impairment or eighth cranial nerve damage.

Biochemical and other tests

Baseline check of auditory and vestibular function	FBC
Bodyweight	LFTs
Electrolytes: serum K, Mg	Renal function: U, Cr, CrCl (or eGFR)

Dose

Standard dose: 1 g daily by IM injection (and not more than 20 mg/kg) for 2–4 months, then 1 g 2–3 times each week.

Dose in renal impairment: there are two similar strategies for dosing in renal impairment:

- The manufacturer recommends doses should be adjusted according to creatinine clearance. The doses in Table C1 are calculated to achieve a mean steady-state capreomycin level of 10 micrograms/mL, at various levels of renal function.
- The British Thoracic Society recommends CrCl >50 mL/minute be dosed daily and CrCl <50 mL/minute be dosed every 48 hours. In both cases the dose should be adjusted according to the capreomycin serum concentration with a desired steady state level of 10 micrograms/mL.¹
- If the patient is receiving haemodialysis, give the dose after a dialysis session.

Creatinine clearance	Dose for these dosing intervals (mg/kg)			
(mL/minute)	24-hourly 48-hourly		72-hourly	
0	1.29	2.58	3.87	
10	2.43	4.87	7.30	
20	3.58	7.16	10.70	
30	4.72	9.45	14.20	
40	5.87	11.70		
50	7.01	14.00		
60	8.16			
80	10.40			
100	12.70			
110	13.90			

Table C1 Capreomycin: dose adjustment according to creatinine clearance

Intramuscular injection

Preparation and administration

- 1. Reconstitute each 1-g vial with 2 mL* NaCl 0.9% or WFI.
- 2. Allow 2-3 minutes for complete dissolution.
- 3. The solution should be clear and colourless to pale straw in colour. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. If giving a 1 g dose*, withdraw the whole vial contents and give by deep IM injection into a large muscle mass.

*If the dose required is other than 1 g the manufacturer recommends the volumes of solvent shown in Table C2 are used to enable withdrawal of the required dose.

Volume of diluent added (mL)	Final volume (mL)	Concentration of capreomycin (mg/mL)		
2.15	2.85	370		
2.63	3.33	310		
3.3	4.0	260		
4.3	5.0	210		

 Table C2
 Capreomycin: Volume of diluent to give desired capreomycin concentrations

Intermittent intravenous infusion (unlicensed in UK)

Preparation and administration

- 1. Reconstitute each 1-g vial with 2 mL* NaCl 0.9% or WFI.
- 2. Allow 2-3 minutes for complete dissolution.
- 3. The solution should be clear and colourless to pale straw in colour. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. If giving a 1 g dose*, withdraw the whole vial contents and add to 100 mL NaCl 0.9%.
- 5. Give by IV infusion over 60 minutes.

*If the dose required is other than 1 g the manufacturer recommends the volumes of solvent shown in Table C2 are used to enable withdrawal of the required dose.

Technical information	
Incompatible with	No information
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, WFl Y-site: No information
рН	4.5-7.5
Sodium content	Nil
Storage	Store below 25°C in original packaging. Vials are for single use only: discard any unused portion.
Displacement value	0.7 mL/vial
Stability after preparation	From a microbiological point of view, should be used immediately; however, may be stored below 25°C for 24 hours. A pale straw colour may develop which may darken over time, but this is not harmful.

Monitoring

Measure	Frequency	Rationale
U&Es	At least monthly (more frequently in renal impairment, especially after initiation)	 Capreomycin is nephrotoxic. †Serum creatinine may indicate toxicity and require a dose reduction. Severe JK, JMg and JCa may occur in overdose. Proteinuria and the presence of casts, erythrocytes, and leucocytes in the urine are also indicative of nephrotoxicity.

(continued)

Monitoring (continued)			
Measure	Frequency	Rationale	
Vestibular and auditory function	Periodically	 Ototoxicity is a potential effect of overexposure to capreomycin. Deterioration of balance or hearing may be indicative of toxic levels. Perform an audiogram if ototoxicity suspected. Some authorities suggest that an audiogram be performed every 2 months. 	
LFTs		 Abnormal results have occurred especially if capreomycin is given in combination with other antituberculous agents that are known to cause hepatic function changes. 	
FBC		 Leucocytosis, leucopenia and eosinophilia have been observed and rarely thrombocytopenia. 	
Capreomycin serum concentration	Only if appropriate. Take sample in the middle of a dosage interval.	 May be measured to check that the desired steady-state concentration of 10 micrograms/mL is achieved, especially in renal impairment. 	
Additional infor	mation		
Common and serious undesirable effects	Injection-related: Local: Pain and induration at injection site. Other: Hypersensitivity reactions including urticaria and rashes, leucocytosis or leucopenia, electrolyte disturbances, hearing loss with tinnitus and vertigo, neuromuscular block after large doses.		
Pharmacokinetics	Elimination half-life is 4-6 hours; up to 55 hours in severe renal impairment.		
Significant interactions	No significant interactions.		
Action in case of overdose	Symptoms to watch for: 1K, 1Ca, 1Mg and other electrolyte disturbances. Antidote: No known antidote but haemodialysis may be effective. Stop administration and give supportive therapy as appropriate.		
Counselling	Patients should report any c	leterioration in balance or hearing.	
Risk rating: AMBER	Score = 4 Moderate-risk product: Ris	k-reduction strategies are recommended.

Bibliography

SPC Capreomycin injection, King Pharmaceuticals Ltd (accessed 16 July 2010).

Carbetocin

100 micrograms/mL solution in 1-mL ampoules

- · Carbetocin is a synthetic analogue of oxytocin, with a longer duration of action.
- It is used to prevent loss of uterine muscle tone and postpartum haemorrhage following Caesarean section under spinal or epidural anaesthesia.
- Carbetocin must **not** be used at any stage of labour before delivery of the infant, as it has a
 prolonged effect on the uterus that may last for several hours following a single IV injection.

Pre-treatment checks

- · Do not give during pregnancy and labour before delivery of the infant.
- · Do not use for the induction of labour or in pre-eclampsia or eclampsia.
- Avoid use in serious cardiovascular disorders and in epilepsy.
- · Contraindicated in hepatic and renal impairment.
- Carbetocin has some vasopressin activity (<0.025 units per 1-mL ampoule), so caution should be
 exercised when using in any pre-existing condition where the rapid increase of extracellular water,
 and associated 1Na may be hazardous to the patient (e.g. cardiovascular disease, epilepsy, asthma,
 migraine, pre-eclampsia or eclampsia).

Biochemical and other tests

Electrolytes: serum Na, K FBC LFTs Maternal blood pressure Renal function: U, Cr, CrCl (or eGFR)

Dose

Standard dose: 100 micrograms (1 mL) by IV injection, immediately post-delivery by Caesarean section and preferably prior to removal of placenta. No further doses should be given.

Intravenous injection

- 1. Withdraw 100 micrograms (1 mL).
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present. Do not dilute prior to use.
- 3. Give by IV injection over 1 minute.

Technical information		
Incompatible with	No information	
Compatible with	Flush: NaCl 0.9% Solutions: No information Y-site: No information	
рН	3.5-4.5	
Sodium content	Negligible	
Storage	Store at 2-8° C in original packaging. Do not freeze.	

Monitoring

Measure	Frequency	Rationale
Postpartum haemorrhage	Postpartum	 If carbetocin has been ineffective in controlling excessive bleeding postpartum, alternative therapy with oxytocin and/or ergometrine may be required once the cause has been determined.
U&Es	Daily in immediate post-Caesarean period	 Carbetocin has some vasopressin activity, and as a result can cause 1Na. Symptomatic signs of 1Na should also be monitored, e.g. drowsiness, listlessness, headache (all early warning signs to be monitored to prevent seizure activity and coma).
FBC		• Anaemia reported in some patients receiving carbetocin.

Additional information

Common and serious undesirable effects	Nausea, vomiting, abdominal discomfort, flushing, LBP, headache, tremor, pruritus, metallic taste, †pulse, chest pain, dyspnoea, dizziness, back pain, anaemia, sweating, chills.
Pharmacokinetics	Elimination half-life is 40 minutes.
Significant interactions	No significant interactions.
Action in case of overdose	Symptomatic and supportive therapy should be provided (oxygen, restricted fluid intake, diuresis, correction of electrolyte imbalances and convulsion control).
Counselling	Small amounts of carbetocin pass into breast milk. It is assumed that any transferred carbetocin is degraded by enzymes in the infant's digestive tract.

122 | Carbetocin | Carboprost

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Bibliography

SPC Pabal 100 micrograms in 1 mL solution for injection (accessed 29 September 2009).

Carboprost

250 micrograms/mL solution in ampoules

- Carboprost trometamol is a synthetic analogue of prostaglandin F2 alpha (dinoprost).
- It is used to treat postpartum haemorrhage due to loss of uterine muscle tone, refractory to firstline treatments with oxytocic agents and/or ergometrine.
- Carboprost has also been used for the termination of pregnancy in the second trimester (between 13 and 20 weeks' gestation) and as a bladder instillation for the treatment of cyclophosphamideinduced haemorrhagic cystitis (both unlicensed).
- Doses are expressed in terms of the base: Carboprost 1 microgram ≅ 1.3 micrograms carboprost trometamol.

Pre-treatment checks

- Contraindicated in known cardiac, pulmonary, renal or hepatic disease and in acute pelvic inflammatory disease.
- · Caution in patients with asthma, diabetes, jaundice and epilepsy.

Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure (caution in hypo/hypertension) LFTs FBC (caution in presence of anaemia) Renal function: U, Cr, CrCl (or eGFR) Intraocular pressure (caution in patients with †intraocular pressure/glaucoma)

Dose

Postpartum haemorrhage: 250 micrograms by deep IM injection, followed as clinically required by up to seven further 250-microgram doses at intervals of approximately 90 minutes (maximum total carboprost dose 2 mg). In severe cases, at the discretion of an expert attending clinician, the interval between doses may be reduced, but must not be less than 15 minutes.

Intramuscular injection

- 1. Ideally, allow injection to reach room temperature before administration.
- 2. Withdraw the required dose.
- 3. Give by deep IM injection. Rotate injection sites for subsequent injections.

Technical information Incompatible with Not relevant Compatible with Not relevant pH 7-8 Sodium content Negligible Excipients Contains benzyl alcohol. Storage Store at 2-8°C.

Monitoring

Measure	Frequency	Rationale
Physical signs of successful treatment	Ongoing during treatment	 Monitor patient for signs of improvement in postpartum bleeding.
Maternal arterial oxygen saturation and respiration		 Recommended in patients with pre-existing cardiopulmonary disease, as carboprost may reduce maternal arterial oxygen levels and oxygen support may be required. Monitor for bronchospasm or dyspnoea.
Maternal temperature		 Carboprost may induce hyperthermia, which would need symptomatic management. Consider reduced frequency or discontinuation of treatment if severe.
Maternal blood pressure	Ongoing during treatment	 ↑BP may occur, consider reduced frequency or discontinuation of treatment if severe.
Cardiac monitoring	Ongoing at discretion of clinician	 Cardiovascular collapse, although rare, is possible following treatment with carboprost.
FBC	During admission	Leucocytosis has been reported: monitor WCC count.
Additional information		

Common and serious undesirable effects	Immediate: Bronchospasm and dyspnoea have been reported. Injection/infusion-related: Local: Injection site erythema and pain. Other: Nausea, vomiting, diarrhoea (pre-treatment with antiemetics and antidiarrhoeals may help), hyperthermia, flushing, †BP, pulmonary oedema, chills, headache, excessive sweating, dizziness.
Pharmacokinetics	Peak plasma concentrations attained in 20-30 minutes. Elimination half-life has not been studied.
Significant interactions	Carboprost may ↑effect of oxytocin.

124 | Carboprost | Caspofungin

Additional information (continued)		
Action in case of overdose	<i>Symptoms to watch for</i> : Excessive doses may cause uterine rupture. <i>Antidote</i> : No known antidote. Stop administration and give supportive therapy as appropriate.	
Counselling	No adverse effects to the nursing infant are anticipated.	
Risk rating: GREEN	Score = 1 Lower-risk product: Risk-reduction strategies should be considered.	
This assessment is based on the full range of proparation and administration entions described in the		

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Bibliography

SPC Hemabate sterile solution (accessed 29 September 2009).

Caspofungin

50-mg and 70-mg dry powder vials

- · Caspofungin acetate is a semisynthetic echinocandin antifungal agent.
- It is used in the treatment of invasive aspergillosis in patients who are refractory to or intolerant of
 other therapy. It is also used in the treatment of invasive candidiasis and as empirical therapy for
 presumed fungal infections in febrile, neutropenic patients.
- Doses are expressed in terms of the base: Caspofungin 70 mg ≅ 77.7 mg caspofungin acetate.

Pre-treatment checks

Do not give in fructose intolerance.

Biochemical and other tests

FBC LFTs

Dose

Adults \leq 80 kg: 70 mg by IV infusion on the first day then 50 mg by IV infusion once daily. Adults >80 kg: 70 mg by IV infusion once daily.

Dose in hepatic impairment: adjusted according to Child-Pugh score:

- Child–Pugh Class A: dose as in normal hepatic function.
- Child-Pugh Class B: 70 mg on first day then 35 mg once daily.
- · Child-Pugh Class C: there is no experience of dosing in severe hepatic impairment.

Intermittent intravenous infusion

Preparation and administration

Caspofungin is incompatible with Gluc solutions.

- 1. Allow to reach room temperature then reconstitute each vial with 10.5 mL WFI.
- 2. Mix gently to obtain a clear solution containing 5 mg/mL (50-mg vial) or 7 mg/mL (70-mg vial).
- Visually inspect the infusion solution for particulate matter or discoloration discard if present.
- 4. Withdraw the required dose and add to 250 mL NaCl 0.9% or Hartmann's.
- 5. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 6. Give by IV infusion over 60 minutes.

Fluid restriction: 50 mg and 35 mg doses (but not 70 mg) may be given in 100 mL NaCl 0.9% or Hartmann's in fluid-restricted patients.

Technical information		
Incompatible with	Caspofungin is incompatible with Gluc solutions. Otherwise no information.	
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Hartmann's Y-site: No information	
рН	6.6	
Sodium content	Negligible	
Excipients	Contains sucrose.	
Storage	Store at 2-8°C in original packaging.	
Displacement value	Not relevant. The vial contains an overage so that the final solution contains 5 mg/mL (50-mg vial) or 7 mg/mL (70-mg vial) when reconstituted as directed.	
Stability after reconstitution	From a microbiological point of view, should be used immediately; however: Reconstituted vials may be stored at 2-8°C for 24 hours. Prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours. Check that the solution is clear before use.	
126 | Caspofungin

Monitoring			
Measure	Frequency	Rationale	
LFTs	Periodically	 Commonly increases in AST, ALT, Alk Phos, direct and total bilirubin are observed. If the Child-Pugh score changes in hepatic impairment, a dose adjustment may be necessary. 	
U&Es		- $\uparrow Cr, \ \downarrow K \ and \ \downarrow Na \ occur \ commonly.$	
FBC		 ↓Hb, ↓haematocrit, ↓WCC, ↓platelets and ↓neutrophils observed commonly while eosinophils are often increased. Neutrophil count is also a measure of therapeutic efficacy. 	
Urinalysis		 îRed blood cells, protein and white blood cells sometimes observed in urine.

Caspofungin may <i>levels</i> or effect of tacrolimus (monitor levels). 	
Action in case of overdose	No specific an	No specific antidote. Caspofungin is not dialysable.	
Risk rating: AMBER	Score = 4 Moderate-risk	Score = 4 Moderate-risk product: Risk-reduction strategies are recommended.	

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Bibliography

SPC CANCIDAS (formerly Caspofungin MSD) (accessed 9 March 2010).

Cefotaxime

500-mg, 1-g, 2-g dry powder vials

- Cefotaxime sodium is a third-generation cephalosporin.
- It is used in the treatment of infections due to susceptible organisms, especially serious and lifethreatening infections.
- Doses are expressed in terms of cefotaxime: Cefotaxime 1 g ≅ 1.05 g cefotaxime sodium.

Pre-treatment checks

- Do not give if there is known hypersensitivity to cefotaxime, cephalosporins or previous immediate hypersensitivity reaction to penicillins or any other beta-lactam antibiotic.
- Do not give in severe heart failure and in patients with an un-paced heart block.

Biochemical and other tests

FBC LFTs Renal function: U, Cr, CrCl (or eGFR)

Dose

Mild to moderate infections: 1 g by IM or IV injection or IV infusion every 12 hours.

Severe infections: 2 g by IV injection or infusion four times daily. Higher doses up to 12 g daily in 3–4 divided doses may be required.

Gonorrhoea: 500 mg by IM or IV injection as a single dose.

Bacterial meningitis: cefotaxime is given before urgent transfer to hospital if benzylpenicillin cannot be given. Suitable doses are: adult and child over 12 years 1 g; child under 12 years 50 mg/kg. (Chloramphenicol may be used if there is a history of anaphylaxis to penicillins or cephalosporins.)

Dose in renal impairment: adjusted according to creatinine clearance:

- CrCl < 5 mL/minute: 1 g loading dose then maintenance of 50% of appropriate normal dose.

Intravenous injection

Preparation and administration

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Reconstitute each 500-mg vial with 2 mL WFI (use 4 mL for each 1-g vial; 10 mL for each 2-g vial) and shake well.
- 2. Withdraw the required dose.
- The solution should be clear and straw-coloured. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over 3-5 minutes.

Intermittent intravenous infusion

Preparation and administration

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Reconstitute each 500-mg vial with 2 mL WFI (use 4 mL for each 1-g vial; 10 mL for each 2-g vial) and shake well.
- Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually 100 mL NaCl 0.9%).
- The solution should be clear and straw-coloured. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 20-60 minutes.

Intramuscular injection

Preparation and administration

- 1. Reconstitute each 500-mg vial with 2 mL WFI (use 4 mL for each 1-g vial; 10 mL for each 2-g vial) and shake well.
- 2. Withdraw the required dose.
- 3. Give by deep IM injection into a large muscle mass. Doses of 2 g should be distributed between two injection sites. Rotate injection sites for subsequent injections. If pain occurs, 1% lidocaine may be used for reconstitution (see the Lidocaine monograph for cautions and monitoring).

Technical inform	ation

Cefradine (cephradine)

500-mg, 1-g dry powder vials

- · Cefradine is a first-generation cephalosporin.
- It is used for infections of the respiratory and urinary tracts and of the skin and soft tissues, and is also used for surgical infection prophylaxis.

Pre-treatment checks

Do not give if there is known hypersensitivity to cefradine, cephalosporins or previous immediate hypersensitivity reaction to penicillins, any other beta-lactam antibiotic or L-arginine.

Biochemical and other tests

FBC LFTs Renal function: U, Cr, CrCl (or eGFR)

Dose

Standard dose: 500 mg-1 g by IM or IV injection or IV infusion every 6 hours.

Severe infections: up to 2 g by IV injection or infusion every 6 hours (or up to 8 g/day if giving by continuous IV infusion).

Surgical prophylaxis: 1-2 g by IM or IV injection at induction. Check local policies.

Dose in renal impairment: adjusted according to creatinine clearance:¹

- CrCl >20-50 mL/minute: dose as in normal renal function.
- CrCl 10-20 mL/minute: dose as in normal renal function.
- CrCl <10 mL/minute: 250–500 mg every 6 hours.

Intramuscular injection

Preparation and administration

- 1. Reconstitute each 500-mg vial with 2 mL WFI or NaCl 0.9% (use 4 mL for each 1-g vial) and shake well.
- 2. Withdraw the required dose.
- 3. Give by deep IM injection. Avoid SC injection as this has resulted in sterile abscess.

Intravenous injection

Preparation and administration

- 1. Dissolve the contents of each 500-mg vial in 5 mL NaCl 0.9% or WFI (use 10 mL for each 1-g vial).
- The solution should be clear and light to straw yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 3-5 minutes.

Intermittent intravenous infusion

Preparation and administration

- 1. Dissolve the contents of each 500-mg vial in 5 mL of a compatible solution (use 10 mL for each 1-g vial).
- Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually 100 mL NaCl 0.9%).

- 3. The solution should be clear and light to straw yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over at least 30 minutes.

Cefradine is also licensed for continuous infusion: if it is being given continuously, replace 5% infusions every 10 hours and 1% infusions every 12 hours with freshly prepared solutions. Protect infusion from strong light and direct sunlight.

Technical information		
Incompatible with	No information	
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, WFl Y-site: No information	
рН	3.5-6.0	
Sodium content	Nil	
Excipients	Contains Larginine (may cause hypersensitivity reactions).	
Storage	Store below 25°C in original packaging.	
Displacement value	 There is an overage of cefradine in each vial. To make 100 mg/mL from a 500-mg vial, add 4.95 mL of diluent. To make 200 mg/mL from a 1-g vial, add 4.45 mL of diluent.² 	
Stability after preparation	 From a microbiological point of view, should be used immediately; however: Reconstituted vials may be stored at 2-8°C for 12 hours. Prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours. 	

Monitoring

Measure	Frequency	Rationale
U&Es	Periodically	• Urea and creatinine occasionally rise. If renal function changes a dose adjustment may be necessary.
LFTs		- Can rarely cause \uparrow AST, ALT, Alk Phos and bilirubin.
FBC		Can rarely can cause neutropenia, leucopenia and eosinophilia.

Ceftazidime

250-mg, 500-mg, 2-g, 3-g dry powder vials; 2-g dry powder vial with transfer needle

- · Ceftazidime pentahydrate is a semisynthetic third-generation cephalosporin.
- It is used in the treatment of susceptible infections especially those due to Pseudomonas spp.
- Doses are expressed in terms of ceftazidime: Ceftazidime 1 g ≡ 1.16 g ceftazidime pentahydrate.

Pre-treatment checks

Do not give if there is known hypersensitivity to ceftazidime or cephalosporins, or previous immediate hypersensitivity reaction to penicillins or any other beta-lactam antibiotic.

Biochemical and other tests

FBC	PT (possibly, see Monitoring)
LFTs	Renal function: U, Cr, CrCl (or eGFR)

Dose

Standard dose: 1 g by IM or IV injection every 8 hours or 2 g by IV injection or infusion every 12 hours.

Severe infections: 2 g by IV injection or infusion every 8–12 hours or 3 g every 12 hours. Urinary tract and less serious infections: 500 mg–1 g by IM or IV injection every 12 hours. Pseudomonal lung infection in cystic fibrosis: up to 50 mg/kg by IV injection or infusion every 8 hours.

Surgical prophylaxis – prostatic surgery: 1 g at induction of anaesthesia repeated if necessary when catheter removed. Check local policy.

Dose in renal impairment: adjusted according to creatinine clearance:¹

- CrCl >50 mL/minute: dose as in normal renal function.
- CrCl 31-50 mL/minute: 1-2 g every 12 hours.
- CrCl 16-30 mL/minute: 1-2 g every 24 hours.
- CrCl 6-15 mL/minute: 500 mg-1 g every 24 hours.
- CrCl <5 mL/minute: 500 mg-1 g every 48 hours.

Intravenous injection

Preparation and administration

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Insert the syringe needle through the vial closure and inject 5 mL WFI into each 500-mg vial; 10 mL WFI into each 1-g or 2-g vial; 15 mL WFI into each 3-g vial.
- 2. Remove the needle and shake to dissolve. CO_2 is released and a clear solution should develop in about 1–2 minutes.
- Invert the vial and, with syringe plunger fully depressed, insert the needle through the vial closure and withdraw all the solution into the syringe. Ensure that the needle does not enter the head space.
- 4. Expel any small bubbles of CO2 present in the syringe.
- The solution should be clear and light yellow to amber. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 6. Give by IV injection over 3-5 minutes.

Intermittent intravenous infusion

Preparation and administration

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- Insert the syringe needle through the vial closure and inject 10 mL WFI into each 2-g vial; 15 mL WFI into each 3-g vial.
- 2. Remove the needle and shake to dissolve: CO_2 is released and a clear solution should develop in about 1–2 minutes.
- 3. Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually 100 mL NaCl 0.9%). Use a minimum 50 mL for a 2-g dose; 100 mL for a 3-g dose.
- 4. Give by IV infusion over 20-30 minutes.

Intramuscular injection (maximum dose 1 g)

Preparation and administration

- 1. Insert the syringe needle through the vial closure and inject 1.5 mL WFI into each 500-mg vial; 3 mL WFI into each 1-g vial.
- 2. Remove the needle and shake to dissolve. $\rm CO_2$ is released and a clear solution should develop in about 1–2 minutes.
- 3. Invert the vial and with syringe plunger fully depressed, insert the needle through the vial closure and withdraw all the solution into the syringe. Ensure that the needle does not enter the head space.
- 4. Expel any small bubbles of CO₂ present in the syringe.
- 5. Give by IM injection into a large muscle such as the gluteus or the lateral aspect of the thigh. Rotate injection sites for subsequent injections. If pain occurs, 0.5–1% lidocaine may be used for reconstitution (see the Lidocaine monograph for cautions and monitoring).

Technical info	rmation
Incompatible with	Sodium bicarbonate. Acetylcysteine, amikacin, amiodarone, amphotericin, cisatracurium, clarithromycin, dobutamine, erythromycin lactobionate, fluconazole, gentamicin, midazolam, pantoprazole, phenytoin sodium, propofol, tobramycin, vancomycin.

Sodium content	2.3 mmol/g
Storage	Store below 25°C in original packaging.
Displacement value	There is considerable variation between brands and within brands, and whether for IM or IV use - see individual SPCs for details.
Stability after preparation	 From a microbiological point of view, should be used immediately; however: Reconstituted vials may be stored 2-8°C for 24 hours. Prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours.

Monitoring		
Measure	Frequency	Rationale
Serum ceftazidime level	If indicated	 Patients on high doses for severe infections and with renal impairment, should have a trough level ≤40 mg/L.
U&Es	Periodically	 Transient rises in urea and creatinine may occur. Deterioration in renal function may require a dose reduction.
FBC		• Eosinophilia, thrombocytosis, leucopenia, neutropenia, and thrombocytopenia may occur.
LFTs		• Transient rises in ALT, AST, GGT, Alk Phos and bilirubin may occur.
Prothrombin time	lf indicated and in at-risk individuals	 A slight prolongation of prothrombin time occurs rarely. Patients with impaired vitamin K synthesis or low vitamin K stores, e.g. patients with chronic hepatic disease or malnutrition may need a 10-mg weekly dose of vitamin K.
Signs of supra-infection or superinfection	Throughout treatment	 May result in the overgrowth of non-susceptible organisms - appropriate therapy should be commenced; treatment may need to be interrupted.
Development of diarrhoea	Throughout and up to 2 months after treatment	 Development of severe, persistent diarrhoea may be suggestive of <i>Clostridium difficile</i>-associated diarrhoea and colitis (pseudomembranous colitis). Discontinue drug and treat. Do not use drugs that inhibit peristalsis.

Additional information

Common and serious undesirable effects	Immediate: Anaphylaxis and other hypersensitivity reactions have been reported. Injection/infusion-related: Local: Thrombophlebitis following IV injection; pain and/or inflammation after IM injection. Other: Nausea, vomiting, abdominal pain, diarrhoea, urticaria, pruritus.
Pharmacokinetics	Elimination half-life is 2 hours.
Significant interactions	 Ceftazidime may <i>îlevels</i> or effect of the following drugs (or <i>îside-effects</i>): acenocoumarol (monitor INR), warfarin (monitor INR).
Action in case of overdose	General symptomatic and supportive methods, together with specific measures to control any seizures. Ceftazidime can be removed by haemodialysis and haemoperfusion.
Counselling	Women taking the combined contraceptive pill should be should be advised to take additional precautions during and for 7 days after the course.

136 | Ceftazidime | Ceftriaxone

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Ceftriaxone

250-mg, 1-g, 2-g dry powder vials

- · Ceftriaxone sodium is a third-generation cephalosporin.
- It is used in the treatment of infections due to susceptible organisms, especially serious and lifethreatening infections.
- Doses are expressed in terms of ceftriaxone: Ceftriaxone 1 g \cong 1.19 g ceftriaxone sodium.

Pre-treatment checks

Do not give if there is known hypersensitivity to ceftriaxone, cephalosporins or previous immediate hypersensitivity reaction to penicillins or any other beta-lactam antibiotic.

Biochemical and other tests

FBC	PT (possibly, see monitoring)
LFTs	Renal function: U, Cr, CrCl (or eGFR)

Dose

Standard dose: 1 g by IM or IV injection daily.

Severe infections: 2-4 g by IV infusion daily.

Uncomplicated gonorrhoea: 250 mg by IM injection as a single dose.

Surgical prophylaxis: 1 g by IM or IV injection at induction; colorectal surgery 2 g by IM injection or IV infusion at induction. Check local policies.

Dose in renal impairment: adjusted according to creatinine clearance:

- CrCl ≥10 mL/minute: dose as in normal renal function.
- CrCl <10 mL/minute: maximum 2 g every 24 hours.

Intravenous injection (doses up to 1 g)

Preparation and administration

Ceftriaxone is incompatible with Ca-containing solutions, e.g. Hartmann's, Ringer's.

- 1. Reconstitute each 1-g vial with 10 mL WFI.
- The solution should be clear and light yellow to amber. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over a minimum of 2-4 minutes.

Intermittent intravenous infusion

Preparation and administration

Ceftriaxone is incompatible with Ca-containing solutions, e.g. Hartmann's, Ringer's.

- 1. Reconstitute each 1-g vial with 10 mL WFI.
- Withdraw the required dose and add to 50–100 mL compatible infusion fluid (usually NaCl 0.9%). Alternatively, reconstitute each 2-g vial with 40 mL of compatible infusion fluid (usually NaCl 0.9%) and infuse directly from the vial.
- The solution should be clear and light yellow to amber. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over at least 30 minutes.

Intramuscular injection

Preparation and administration

- 1. Reconstitute each 250-mg vial with 1 mL lidocaine 1% (use 3.5 mL for a 1-g vial). The injection is painful if not given with lidocaine (see the Lidocaine monograph for cautions and monitoring).
- 2. Withdraw the required dose.
- 3. Aspirate before injection to avoid inadvertent intravascular injection.
- 4. Give by deep IM injection. Doses >1 g should be distributed between two injection sites.

lechnical information		
Incompatible with	Ceftriaxone is incompatible with Ca-containing solutions, e.g. Hartmann's, Ringer's. Fatalities have occurred in neonates and infants due to precipitates forming in lungs and kidneys. Aminophylline, amphotericin, clindamycin phosphate, fluconazole, gentamicin, labetalol, tobramycin, vancomycin.	
Compatible with	Flush: NaCl 0.9% Solutions: Gluc 5%, NaCl 0.9%, Gluc-NaCl (all with added KCl) Y-site: Aciclovir, amikacin, aztreonam, cisatracurium, granisetron, metronidazole, pantoprazole, propofol, remifentanil, sodium bicarbonate, tigecycline	
рН	6-8	
Sodium content	3.6 mmol/g	
Storage	Store below 25°C in original packaging.	

138 | Ceftriaxone

Technical information (continued)			
Displacement value	0.194 mL/250 mg (Rocephin) 0.5 mL/g with WFI, 0.55 mL/g with lidocaine 1% (Wockhardt)		
Stability after preparation	 From a microbiological point of view, should be used immediately; however: Reconstituted vials may be stored at 2-8°C for 24 hours. Prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours. 		
Monitoring			
Measure	Frequency	Rationale	
Ceftriaxone serum concentration	Regularly if treatment prolonged	 For patients with severe renal impairment and concomitant hepatic insufficiency (it is eliminated by both routes, each of which normally compensates for a deficiency in the other) and in patients receiving dialysis, serum concentration should be checked regularly and dosage adjusted if necessary. In a healthy adult the mean peak concentration is about 200 mg/L after a 1-g IV injection and about 250 mg/L 30 minutes after a 2-g infusion. 	
U&Es	Periodically	 Urea and creatinine occasionally rise. If renal function changes, a dose adjustment may be necessary. 	
FBC		 Rarely can cause neutropenia, leucopenia, eosinophilia, thrombocytopenia, anaemia. 	
LFTs		 Rarely <i>AST</i>, ALT, Alk Phos and bilirubin. If this is severe and renal function is impaired, a dose reduction may be necessary. 	
Prothrombin time	If indicated and in at-risk individuals	 A slight prolongation of prothrombin time occurs rarely. Patients with impaired vitamin K synthesis or ↓vitamin K stores, e.g. patients with chronic hepatic disease or malnutrition, may need a 10-mg weekly dose of vitamin K. 	
Development of signs and symptoms of gallbladder disease	Throughout treatment	 The drug can precipitate in the gallbladder. Discontinuation and conservative management should be considered if this occurs. 	
Signs of supra-infection or superinfection	Throughout treatment	 The drug may result in the overgrowth of non-susceptible organisms - appropriate therapy should be commenced; treatment may need to be interrupted. 	
Development of diarrhoea	Throughout and up to 2 months after treatment	 Development of severe, persistent diarrhoea may be suggestive of <i>Clostridium difficile</i>- associated diarrhoea and colitis (pseudomembranous colitis). Discontinue drug and treat. Do not use drugs that inhibit peristalsis. 	

Additional information		
Common and serious undesirable effects	Immediate: Anaphylaxis and other hypersensitivity reactions have been reported. Injection/infusion-related: Local: Phlebitis and pain following IV injection. Other: Nausea, vomiting, abdominal pain, diarrhoea, urticaria, pruritus.	
Pharmacokinetics	Elimination half-life is 5.8-8.7 hours.	
Significant interactions	 Ceftriaxone may <i>îlevels</i> or effect of the following drugs (or <i>îside-effects</i>): acenocoumarol (monitor INR), warfarin (monitor INR). 	
Action in case of overdose	There is no specific antidote; treatment should be symptomatic.	
Counselling	Women taking the combined contraceptive pill should be should be advised to take additional precautions during and for 7 days after the course.	

Risk rating: GREEN

 $\label{eq:score} \begin{array}{l} \mbox{Score} = 2 \\ \mbox{Lower-risk product: Risk-reduction strategies should be considered.} \end{array}$

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Bibliography

SPC Ceftriaxone 1 g, 2 g powder for solution for injection (Wockhardt UK Ltd) (accessed 3 March 2009). SPC Rocephin 250mg, 1 g and 2 g vials (accessed 3 March 2009).

Cefuroxime

250-mg, 750-mg, 1.5-g dry powder vials

- Cefuroxime sodium is a second-generation cephalosporin.
- It is used in the treatment of susceptible infections causing lower respiratory tract infections (including pneumonia), serious skin and skin structure infections, genitourinary tract infections, bone and joint infections, septicaemia and meningitis.
- Doses are expressed in terms of cefuroxime: Cefuroxime $1 g \cong 1.05 g$ cefuroxime sodium.

Pre-treatment checks

Do not give if there is known hypersensitivity to cefuroxime, cephalosporins or previous immediate hypersensitivity reaction to penicillins or any other beta-lactam antibiotic.

Biochemical and other tests

FBC	Prothrombin time (possibly, see monitoring)
LFTs	Renal function: U, Cr, CrCl (or eGFR)

Dose

Standard dose: 750 mg by IM or IV injection or IV infusion every 6-8 hours.

Severe infections: 1.5 g by IV injection or infusion every 6-8 hours.

Gonorrhoea: 1.5 g as a single dose by IM injection (divided between two sites). An oral dose of 1 g probenecid may also be given (to slow the rate of tubular secretion of cefuroxime).

Surgical prophylaxis: 1.5 g by IV injection at induction; up to three further doses of 750 mg may be given by IM or IV injection every 8 hours for high-risk procedures. Check local policies.

Meningitis: 3 g by IV injection or infusion every 8 hours.

Dose in renal impairment: adjusted according to creatinine clearance:

- CrCl >50 mL/minute: dose as in normal renal function.
- CrCl 20-50 mL/minute: 750 mg-1.5 g every 8 hours.
- CrCl 10-20 mL/minute: 750 mg-1.5 g every 8-12 hours.
- CrCl <10 mL/minute: 750 mg-1.5 g every 12-24 hours.

Intravenous injection

Preparation and administration

- Reconstitute each 750-mg vial with 6–10 mL WFI (use 15–20 mL for each 1.5-g vial) and shake gently.
- 2. Withdraw the required dose.
- The solution should be clear and colourless to brownish yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over 3-5 minutes.

Intermittent intravenous infusion

Preparation and administration

- 1. Reconstitute each 750-mg vial with 6–10 mL WFI (use 15–20 mL for each 1.5-g vial) and shake gently.
- Withdraw the required dose and add to 50–100 mL of compatible infusion fluid (usually NaCl 0.9%).
- The solution should be clear and colourless to brownish yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 30 minutes.

Intramuscular injection (doses up to 750 mg)

Preparation and administration

- Add 3 mL WFI to each 750-mg vial and shake gently to produce a colourless to slightly yellow suspension.
- 2. Withdraw the required dose.
- Give by IM injection into a large muscle such as the gluteus or the lateral aspect of the thigh. Doses >750 mg should be distributed between two injection sites.

Technical information			
Incompatible with	Sodium bicarbonate. Amikacin, ciprofloxacin, cisatracurium, clarithromycin, fluconazole, gentamicin, midazolam, pantoprazole, ranitidine, tobramycin, vancomycin.		
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, Gluc-NaCl, Hartmann's, Ringer's (all including added KCl) Y-site: Aciclovir, clindamycin phosphate, flucloxacillin, furosemide, granisetron, linezolid, metronidazole (in the same bag), ondansetron, propofol, remifentanil, vecuronium bromide		
рН	5.5-8.5		
Sodium content	1.8 mmol/750 mg		
Storage	Store below 25°C in original packaging.		
Displacement value	0.2 mL/250 mg; 0.8 mL/750 mg; 1.5 mL/1.5 g		
Stability after preparation	 From a microbiological point of view, should be used immediately; however: Reconstituted vials may be stored at 2-8°C for 24 hours. Prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours. 		

Monitoring

Measure	Frequency	Rationale
U&Es	Periodically	• Transient rises in urea and creatinine may occur. Deterioration in renal function may require a dose reduction.
FBC		 Can cause neutropenia, eosinophilia and rarely leucopenia, anaemia, laematocrit and thrombocytopenia.
LFTs		• Transient rises in AST, ALT, Alk Phos and bilirubin may occur.
Signs of supra-infection or superinfection	Throughout treatment	 May result in the overgrowth of non-susceptible organisms - appropriate therapy should be commenced; treatment may need to be interrupted.
Development of diarrhoea	Throughout and up to 2 months after treatment	 Development of severe, persistent diarrhoea may be suggestive of <i>Clostridium difficile</i>-associated diarrhoea and colitis (pseudomembranous colitis). Discontinue drug and treat. Do not use drugs that inhibit peristalsis.
Prothrombin time	If indicated and in at-risk individuals	 A slight prolongation of PT occurs rarely. Patients with impaired vitamin K synthesis or low vitamin K stores, e.g. patients with chronic hepatic disease or malnutrition may need a 10-mg weekly dose of vitamin K.

142 | Cefuroxime | Chloramphenicol

Additional information			
Common and serious undesirable effects	Immediate: Anaphylaxis and other hypersensitivity reactions have been reported. Injection/infusion-related: Local: Thrombophlebitis following IV injection; pain and/or inflammation after IM injection. Other: Nausea, vomiting, abdominal pain, diarrhoea, urticaria, pruritus.		
Pharmacokinetics	Elimination half-life is 80 minutes.		
Significant interactions	 Cefuroxime may <i>ilevels</i> or effect of the following drugs (or <i>iside-effects</i>): acenocoumarol (monitor INR), warfarin (monitor INR). 		
Action in case of overdose	In overdose cerebral irritation and seizures may occur (use anticonvulsant therapy if indicated). Cefuroxime can be removed by haemodialysis or peritoneal dialysis.		
Counselling	Women taking the combined contraceptive pill should be should be advised to take additional precautions during and for 7 days after the course.		
Risk rating: GREEN	Score = 2 Lower-risk product: Risk-reduction strategies should be considered.		

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Chloramphenicol

1-g dry powder vials

- · Chloramphenicol sodium succinate is a potent broad-spectrum antibiotic.
- It is used in typhoid, meningitis caused by *Haemophilus influenzae* and other serious infections caused by other sensitive bacteria. However, the risk of life-threatening adverse effects, particularly bone-marrow aplasia, has severely limited the clinical usefulness of chloramphenicol.
- It should **not** be used in the treatment of any infection for which a less-toxic antibiotic is appropriate.
- Doses are expressed in terms of base: Chloramphenicol 1 g \cong 1.4 g chloramphenicol sodium succinate.

Pre-treatment checks

- Do not give if there is known hypersensitivity and/or toxic reaction to chloramphenicol.
- Do not give in acute porphyria.

Biochemical and other tests

FBC LFTs Renal function: U, Cr, CrCl (or eGFR)

Dose

Standard dose: 12.5 mg/kg by IV injection or infusion every 6 hours.

Severe infection, e.g. septicaemia or meningitis: 25 mg/kg by IV injection or infusion every 6 hours, provided dose is reduced as soon as clinically indicated.

To prevent relapse treatment should be continued until apyrexial for 4 days in rickettsial diseases and for 8–10 days in typhoid fever.

Dose in renal impairment: dose as in normal renal function.¹

Dose in hepatic impairment: an initial 1-g loading dose is given followed by 500 mg every 6 hours for an adult (with dose adjustment depending on plasma levels).²

Intravenous injection (preferred method)

Preparation and administration

- 1. Reconstitute each 1-g vial with 9.2 mL WFI, NaCl 0.9% or Gluc 5% to give a solution containing 100 mg/mL.
- 2. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over 1 minute.

Intravenous infusion

Preparation and administration

- 1. Reconstitute each 1-g vial with 9.2 mL WFI, NaCl 0.9% or Gluc 5% to give a solution containing 100 mg/mL.
- 2. Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually 100 mL NaCl 0.9%).
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 10 minutes.

Intramuscular injection (not recommended – absorption can be slow and unpredictable)

Preparation and administration

- 1. Reconstitute each 1-g vial with 1.7 mL WFI, NaCl 0.9% or Gluc 5% to give a solution containing 400 mg/mL.
- 2. Withdraw the required dose.
- 3. Give by deep IM injection.

Technical information			
Incompatible with	Fluconazole, phenytoin sodium, prochlorperazine, vancomycin.		
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, Gluc-NaCl, Hartmann's, Ringer's Y-site: Aciclovir, amikacin, aminophylline, ampicillin, benzylpenicillin, calcium gluconate, colistimethate sodium, dopamine, esmolol, foscarnet, hydrocortisone sodium succinate, labetalol, magnesium sulfate, methylprednisolone sodium succinate, metronidazole, phytomenadione, ranitidine, sodium bicarbonate, verapamil		
рН	6.4-7		
Sodium content	3.14 mmol/g		
Storage	Store below 25°C in original packaging.		
Displacement value	0.8 mL/vial		
Stability after reconstitution	 From a microbiological point of view, should be used immediately; however: Reconstituted vials may be stored at room temperature for 24 hours. Prepared infusions may be stored at room temperature and given within 24 hours. 		

Monitoring

Measure	Frequency	Rationale
FBC	Every 2 days	 Can cause severe bone marrow depression leading to reticulocytopenia, leucopenia, thrombocytopenia, anaemia and other haematological abnormalities. More common with high dose, prolonged therapy or repeated courses. Discontinue therapy immediately if these occur.
LFTs	No specific periodicity but may be apt with FBC	 Changes in hepatic function (bilirubin is the best indicator) may require a dose adjustment.
U&Es		 Changes in renal function may require a dose adjustment.
Chloramphenicol plasma concentration	Every 2-3 days (usually only required in elderly patients and in hepatic impairment)	 A trough level is taken just before a dose and should be 5-15 mg/L. A peak level is taken 1 hour after the dose has been given and should be 15-25 mg/L. For meaningful interpretation of results the laboratory request form must state: The time the previous dose was given. The time the blood sample was taken.

(continued)

Monitoring (continued)			
Measure	Frequency	Rationale	
Signs of supra-infection or superinfection	Throughout treatment	 May result in the overgrowth of non-susceptible organisms - appropriate therapy should be commenced; treatment may need to be interrupted. 	
Signs of optic or peripheral neuritis		• More common in high doses. If these symptoms occur discontinue therapy immediately.	
Development of diarrhoea	Throughout and up to 2 months after treatment	 Development of severe, persistent diarrhoea may be suggestive of <i>Clostridium difficile</i>-associated diarrhoea and colitis (pseudomembranous colitis). Discontinue drug and treat. Do not use drugs that inhibit peristalsis.

Bibliography

SPC Kemicetine succinate injection (accessed 3 March 2009).

Chlorphenamine maleate (chlorpheniramine maleate)

10 mg/mL solution in 1-mL ampoules

- Chlorphenamine maleate is a sedating antihistamine that causes a moderate degree of sedation; it also has antimuscarinic activity.
- It is indicated for acute urticaria, control of allergic reactions to insect bites and stings, angioedema, drug and serum reactions, desensitisation reactions, hay fever, vasomotor rhinitis, severe pruritus of non-specific origin.
- It may be given IV as an adjunct in the emergency treatment of anaphylactic shock.

Pre-treatment checks

- Avoid in patients taking monoamine oxidase inhibitors up to 14 days previously because of *\risk* of extrapyramidal side-effects.
- Use with caution in asthma, bronchitis or bronchiectasis as it may thicken secretions.
- Use with care in narrow-angle glaucoma, prostatic hypertrophy, urinary retention and pyloroduodenal obstruction because of its antimuscarinic effects.
- Use with care in epilepsy as it may ↓convulsive threshold.
- Chlorphenamine is thought to be safe in acute porphyria.

Biochemical and other tests

None required.

Dose

Standard dose: 10 mg by SC, IM or IV injection repeated up to four times in 24 hours if required (maximum 40 mg in 24 hours).

Dose in hepatic impairment: avoid in severe liver disease; may cause ↑sedation.

Intravenous injection

Preparation and administration

- 1. Withdraw the required dose. May be diluted to 10 mL with NaCl 0.9% to facilitate slow administration.
- 2. Give by slow IV injection over 1 minute.
- 3. Flush with 5 mL NaCl 0.9%.

Intramuscular injection

Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection into a large muscle such as the gluteus or lateral aspect of the thigh.

Subcutaneous injection

Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by SC injection.

Technical information		
Incompatible with	Noradrenaline (norepinephrine)	
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, Gluc-NaCl, Hartmann's, Ringer's Y-site: No information	
рН	4-5.2	
Sodium content	Negligible	
Storage	Store below 25°C in original packaging.	

Monitoring

Measure	Frequency	Rationale
Blood pressure	Post IV injection	• ↓BP may follow rapid IV injection.

Additional information

Common and serious undesirable effects	 Injection-related: Too rapid administration: Transient ↓BP, paradoxical CNS stimulation. Local: Stinging or burning at the site of injection. Other: Drowsiness, headache, psychomotor impairment, urinary retention, dry mouth, blurred vision
Pharmacokinetics	In adults with normal renal and hepatic function, the half-life of chlorphenamine ranges from 2 to 43 hours. The duration of action is reported as 4-6 hours.
Significant interactions	 Chlorphenamine may <i>îside-effects</i> of the following drugs: MAOIs (<i>îrisk</i> of EPSE; avoid within 14 days), opioid analgesics (<i>îsedation</i>).
Action in case of overdose	Symptoms to watch for: †drowsiness. Antidote: No known antidote; stop administration and give supportive therapy as appropriate.
Counselling	May cause drowsiness; if affected do not drive or operate machinery. Do not drink alcohol for a few hours after injection.

Risk rating: GREEN	Score = 0 Lower-risk product: Risk-reduction strategies should be considered.					

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Bibliography

SPC Chlorphenamine, Link Pharmaceuticals (accessed 3 July 2008).

Chlorpromazine hydrochloride

25 mg/mL solution in 2-mL ampoules

- Chlorpromazine hydrochloride is a phenothiazine antipsychotic with a wide range of actions. It is
 a dopamine inhibitor; it has antiemetic activity; it has muscle relaxant properties; and it inhibits
 the heat-regulating centre.
- It is used to treat schizophrenia and other psychoses. By IM injection it is used to manage severely disturbed, agitated or violent behaviour.
- It is also used for intractable hiccup and to treat nausea and vomiting associated with terminal illness. It has been used to facilitate the induction of hypothermia because it prevents shivering and causes vasodilatation.
- In all cases the injection is intended for short-term treatment until the oral route is available.

Pre-treatment checks

- Do not give to patients with known bone marrow depression.
- Avoid using in patients with renal or hepatic impairment, Parkinson disease, hypothyroidism, cardiac failure, phaeochromocytoma, myasthenia gravis and prostatic hypertrophy.
- Use with caution in patients with a history of narrow-angle glaucoma or agranulocytosis.

Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure	LFTs
ECG	Renal function: U, Cr, CrCl (or eGFR)

Dose

For acute relief of symptoms in schizophrenia, other psychoses, anxiety and agitation: 25–50 mg by deep IM injection every 6 to 8 hours.

For intractable hiccups: 25–50 mg by deep IM injection every 6–8 hours. If this is ineffective, 25–50 mg may be given by slow IV infusion.

For induction of hypothermia to prevent shivering: 25–50 mg by deep IM injection every 6–8 hours.

For nausea and vomiting associated with terminal illness: 25 mg by deep IM injection then 25–50 mg every 3–4 hours until vomiting stops. Transfer to oral therapy as soon as possible.

Intramuscular injection

Preparation and administration

See Special handling below.

Take care to avoid inadvertent SC administration as it is extremely irritant.

- 1. Withdraw the required dose.
- Give by deep IM injection into large muscle such as the gluteal muscle. If irritation at the injection site is a problem the injection may be diluted with NaCl 0.9%.
- 3. Patient should remain supine for 30 minutes after administration.

Intermittent intravenous infusion

Preparation and administration

See Special handling below.

- 1. Withdraw the required dose and add to 500 mL-1L NaCl 0.9%.
- The solution should be clear and colourless to very pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV infusion. Patient should remain supine during administration.

Technical information				
Incompatible with	Amphotericin, aztreonam, furosemide, linezolid, piperacillin with tazobactam, remifentanil, tigecycline.			
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9% Y-site: Cisatracurium, fluconazole, granisetron, hydrocortisone sodium succinate, ondansetron, propofol			
рН	5-6.5			
Sodium content	Negligible			
Excipients	Contains sulfites (may cause allergic reactions).			
Storage	Store below 25°C in original packaging. A slight yellowish discoloration does not indicate loss of potency - markedly discoloured solutions should not be used.			
Special handling	Handle solutions with care to avoid risk of contact sensitisation.			
Stability after preparation	Prepared infusions should be used immediately.			

150 | Chlorpromazine hydrochloride

Monitoring				
Measure	Frequency	Rationale		
Blood pressure	First 30 minutes and periodically	 Patient should remain lying down for 30 minutes after injection and BP should be monitored as ↓BP may occur. 		
Pulse	thereatter it required.	• May cause ↑pulse.		
Injection site	Post administration	 May be painful and may cause nodule formation. 		
EPSE		• May cause extrapyramidal side-effects.		
Therapeutic improvement	Periodically	 Reduction in nausea and vomiting, hiccups or improvement in symptoms of psychotic illness schizophrenia or mania. 		
LFTs	Periodically if on long-term treatment	Stop treatment if jaundice develops.		
Additional i	nformation

Bibliography

SPC Largactil (accessed 2 October 2007).

Ciclosporin (cyclosporine, cyclosporin)

50 mg/mL solution in 1-mL and 5-mL ampoules

- Ciclosporin is an immunosuppressant that appears to act on lymphocytes (mainly helper T-cells), with little effect on bone marrow.
- It is usually given orally, often with corticosteroids and other immunosuppressants, in organ and tissue transplantation for the management or prophylaxis of graft rejection. It is also used in severe forms of atopic dermatitis, psoriasis, rheumatoid arthritis and nephrotic syndrome.
- The IV form is used for patients who cannot tolerate the oral form post surgery or in whom oral absorption may be impaired during episodes of GI disturbance. Patients should be switched to oral therapy as soon as is practical.

Pre-treatment checks

- Do not give if hypersensitive to polyethoxylated castor oils.
- Caution in acute porphyria.
- · Consult product literature for indication-specific cautions.

Biochemical and other tests

Blood pressure Electrolytes: serum K, Mg LFTs Lipid profile Renal function: U, Cr, CrCl (or eGFR)

Dose

For existing patients switched from maintenance to IV dosing: IV dose \equiv maintenance oral dose divided by 3.

Organ transplantation, bone marrow transplantation/prevention and GVHD: 3 mg/kg/ day, from the day before transplantation to 2 weeks until oral maintenance therapy begins. The dose may be lower if given concomitantly with other immunosuppressant therapy.

Refractory ulcerative colitis (unlicensed): 2 mg/kg daily dose adjusted according to blood ciclosporin concentration and response.

152 | Ciclosporin

Intermittent intravenous infusion

Preparation and administration

PVC containers (e.g. Viaflex bags) should not be used as phthalate leaching can occur.

- 1. Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually NaCl 0.9%). Ensure that each 50 mg is diluted in 20–100 mL.
- 2. The solution should be clear and colourless to faintly brown-yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 2–6 hours using a syringe or volumetric pump. Observe for at least 30 minutes after starting infusion and at frequent intervals thereafter.

Technical information			
Incompatible with	PVC containers (e.g. Viaflex bags) should not be used as phthalate leaching can occur. Amphotericin, drotrecogin alfa (activated), magnesium sulfate, pantoprazole.		
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5% Y-site: Linezolid, micafungin, propofol		
рН	6.0-7.0		
Sodium content	Nil		
Excipients	Contains ethanol (may interact with metronidazole, possible religious objections). Contains polyoxyl castor oils (have been associated with severe anaphylactic reactions).		
Storage	Store below 30°C in original packaging. Do not freeze.		
Stability after preparation	From a microbiological point of view, should be used immediately; however, infusions prepared in glass containers may be stored at room temperature and infused within 12 hours.		

Monitoring

Measure	Frequency	Rationale
Blood pressure	Regularly initially then monthly	 ↑BP may develop (treat with antihypertensive drugs as appropriate). Frequency of monitoring may vary with the indication.
U&Es	Weekly for first few weeks then 3-monthly	 Serum Cr and urea may rise (dose adjustment may be necessary). 1K can occur especially with other drugs likely to raise potassium (corrective action may be necessary).

(continued)

Monitoring (continued)				
Measure	Frequency	Rationale		
LFTs	Monthly for 3 months then 3-monthly	Bilirubin and liver enzymes may rise.Dose adjustment may be necessary.		
Serum magnesium	Intermittently	 Clearance of Mg is enhanced (if ↓Mg occurs, treat by supplementation). 		
Lipid profile	6-monthly	 A reversible increase in lipids can occur (compare with baseline measure). 		
Symptoms of infection	Throughout treatment	 Immunosuppression predisposes patients to infection. 		
Ciclosporin level	3 or 4 times weekly during early post transplantation then monthly by 6-12 months post transplantation or if considered necessary. NB: Clearly state time elapsed since last dose given on blood sample.	 There is debate as to whether measurement is necessary; some authorities state desired trough concentrations: 1 month post transplant: not less than 150 nanograms/mL 3 months post transplant: 250-300 nanograms/mL Others state that measuring a level 2 hours after a dose (C₂) is more appropriate. For adult renal transplant recipients desired C₂ concentrations are: 1 month post transplant: 1.5-2 micrograms/mL 2 months post transplant: 1.5 micrograms/mL 3 months post transplant: 1.1 micrograms/mL 4-6 months post transplant: 0.9 micrograms/mL 7-12 months post transplant: 0.8 micrograms/mL >12 months post transplant: 20 micrograms/mL For adult liver transplant: 1 micrograms/mL 6-12 months post transplant: 1 micrograms/mL 6-12 months post transplant: 0.8 micrograms/mL 		
Additional information				
Common and serious undesirable effects	Immediate: Severe anaphylactoid reactions have been reported (reputedly due to polyoxyl castor oil content). Other: Hyperlipidaemia, hyperuricaemia, †K, ↓Mg, tremor, headache, paraesthesia, †BP, anorexia, nausea, vomiting, abdominal pain, diarrhoea, gingival hyperplasia, hepatic dysfunction, hypertrichosis (gonk-like hair), muscle cramps, myalgia, renal dysfunction, fatigue.			
Pharmacokinetics	Elimination half-life is 19 hours.			

(continued)

Additional info	rmation (continued)
Significant interactions	 The following may ↑ciclosporin levels or effect (or ↑side-effects): atazanavir, carvedilol, chloramphenicol, chloroquine, cimetidine, clarithromycin, colchicine, danazol, daptomycin (preferably avoid combination), diltiazem, doxorubicin, doxycycline, erythromycin, ezetimibe, fluconazole, grapefruit juice, hydroxychloroquine, indinavir, itraconazole, ketoconazole, lercanidipine (avoid combination), macrolides, methotrexate, methylprednisolone (risk of convulsions with high doses), metoclopramide, miconazole, nelfinavir, posaconazole, progestogens, quinupristin/dalfopristin, ritonavir, rosuvastatin (avoid combination), saquinavir, tacrolimus (avoid combination), telithromycin, verapamil, voriconazole. The following may cause ↑K with ciclosporin: ACE inhibitors, aldosterone antagonists, angiotensin-II receptor antagonists, potassium salts, potassium-sparing diuretics. The following may ↑risk of nephrotoxicity with ciclosporin: aminoglycosides, amphotericin, colchicine, melphalan, polymyxins, quinolones, sulfonamides, trimethoprim, vancomycin. The following may ↓ciclosporin levels or effect: carbamazepine, barbiturates, bosentan (avoid combination), efavirenz, modafinil, octreotide, phenytoin, primidone, rifampicin, St John's wort (avoid combination), sulfadiazine, sulfinpyrazone, trimethoprim. Ciclosporin may ↑levels or effect of the following drugs (or ↑side-effects): aliskiren (avoid combination), basentan (avoid combination), caspofungin (monitor LFTs), diclofenac (halve diclofenac dose), digoxin, NSAIDs, saquinavir, sitaxentan (avoid combination), statins, vaccines-live attenuated (avoid combination). Injectable preparation contains ethanol: may interact with disulfiram and metronidazole.
Action in case of overdose	Treatment should be symptomatic with general supportive measures. Monitor BP and cardiac rhythm. Ciclosporin is not dialysable and not cleared by charcoal haemoperfusion.
Counselling	Do not take oral form with grapefruit or grapefruit juice. Avoid excessive exposure to UV light including sunlight.
Risk rating: AMBER	Score $= 5$ Moderate-risk product: Risk-reduction strategies are recommended.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Bibliography

SPC SANDIMMUN concentrate for solution for infusion 50 mg/mL [ciclosporin] (accessed 3 March 2009).

Cidofovir

75 mg/mL concentrate for infusion in 5-mL vials

- · Cidofovir is a nucleoside analogue that is active against herpes viruses.
- It is used in the treatment of cytomegalovirus (CMV) retinitis in patients with AIDS for whom other drugs are inappropriate.

Cidofovir is toxic and personnel must be adequately protected during handling and administration – consult product literature.

Pre-treatment checks

- · Do not give if there is known hypersensitivity to cidofovir or probenecid.
- Avoid if CrCl ≤55 mL/minute or proteinuria ≥100 mg/dL (≥2+).
- · Do not use with other potentially nephrotoxic drugs.
- Caution in diabetes mellitus (†risk of ocular hypotony).
- To minimise the risk of nephrotoxicity, ensure that probenecid is co-prescribed and that patient is adequately hydrated with IV fluids.

Biochemical and other tests

Intraocular pressure LFTs Renal function: U, Cr, CrCl (or eGFR) Urine dipstick for protein

Dose

Cidofovir must only be given as an IV infusion and must never be given as a direct intraocular injection.

Cidofovir is nephrotoxic. Acute renal failure has been reported after only one or two doses, and there have been fatalities. To minimise potential nephrotoxicity the patient must be pre-treated with oral probenecid and IV NaCl 0.9% hydration before each dose.

Induction dose: 5 mg/kg by IV infusion once weekly for 2 weeks (with probenecid and IV fluids, see below).

Maintenance dose (beginning 2 weeks after completion of induction): 5 mg/kg by IV infusion once every 2 weeks (with probenecid and IV fluids, see below).

Probenecid co-treatment by mouth (preferably after food to \downarrow **nausea/vomiting):** 2 g 3 hours before cidofovir infusion followed by 1 g at 2 hours and 1 g at 8 hours after the end of cidofovir infusion (total probenecid 4 g). The use of an antiemetic may be necessary if nausea/vomiting are a problem.

Prior hydration by IV infusion: give NaCl 0.9% 1 L over 1 hour immediately before each cidofovir infusion. If tolerated, an additional 1 L may be given over 1–3 hours, starting at the same time as the cidofovir infusion or immediately afterwards.

Dose in renal impairment:

- CrCl >55 mL/minute: dose as in normal renal function.
- * $CrCl \leq 55 \text{ mL/minute: manufacturer advises avoid.}$

Intermittent intravenous infusion

Preparation and administration

Cidofovir infusion should be prepared in a CIVAS unit. See Special handling and Spillage below.

156 | Cidofovir

- 1. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 2. Ensure that prophylactic probenecid and hydration have been given.
- 3. Give the entire volume by IV infusion via a volumetric infusion device over 60 minutes. The infusion must be given at a constant rate. To minimise the risk of nephrotoxicity, the dose must be infused over a minimum of 60 minutes.
- 4. Ensure further prophylactic probenecid and hydration (if appropriate) are given.

Technical information				
Incompatible with	No information			
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9% Y-site: No information			
рН	7.4			
Sodium content	2.5 mmol per 5 mL vial			
Storage	Store below 30°C in original packaging. Do not refrigerate or freeze. Use opened vials immediately and discard any unused solution.			
Special handling	Should be prepared in a CIVAS unit in a laminar flow cabinet and be administered only by clinicians suitably experienced in the care of AIDS patients.			
Spillage	If cidofovir contacts the skin or mucosa, wash thoroughly with water. Excess solution and all other materials used in the preparation and administration should be placed in a leak-proof, puncture-proof container for disposal and in accordance with local policy.			
Stability after preparation	From a microbiological point of view, prepared infusions should be used immediately; however, the preparation may be stored at 2-8°C and infused (at room temperature) within 24 hours (or as guided by CIVAS unit).			

Monitoring

Measure	Frequency	Rationale
Serum creatinine and urine protein	Within 24 hours prior to each dose of cidofovir	 Proteinuria is an early and sensitive indicator of cidofovir-induced nephrotoxicity. If serum creatinine increases by 44 micromol/L (500 micrograms/dL) above baseline, or if persistent proteinuria ≥2+ develops, therapy should be stopped and IV hydration commenced. If following hydration, a ≥2+ proteinuria is still observed, cidofovir therapy should be discontinued. In the USA a reduction of the maintenance dose to 3 mg/kg is permitted for increases in serum creatinine of 300-400 micrograms/dL above baseline.
WCC including differential neutrophil count	Prior to each dose of cidofovir	 Reversible neutropenia sometimes occurs, which may resolve spontaneously whether or not the cidofovir is stopped. Filgrastim (G-CSF) has been used in some patients.

Monitoring (continued)

Monitoring (commond)				
Measure	Frequency	Rationale		
Ophthalmological examination (intraocular pressure, visual acuity, and symptoms of uveitis/iritis)	Regularly	 Iritis/uveitis occur commonly, which may respond to a topical corticosteroid (with or without a cycloplegic drug). Discontinue cidofovir if there is no response to topical corticosteroid or if the condition worsens, or if iritis/uveitis recurs after successful treatment. Intraocular pressure may decrease by up to 50% from pre-treatment baseline. 		
Development of hypersensitivity reaction to probenecid	Throughout treatment	 If rash, fever or chills occur, consider prophylactic or therapeutic use of an antihistamine and/or paracetamol. 		
Additional inform	nation			
Common and serious undesirable effects	Neutropenia, iritis/uveitis; ⊥intraocular pressure, dyspnoea; pneumonia, nausea, vomiting, alopecia, proteinuria; †creatinine, asthenia; fever, death; infection. Rash and fever may also commonly present due to probenecid.			
Pharmacokinetics	Elimination half-life is 2.5 hours (major metabolite 17 hours).			
Significant interactions	 Cidofovir therapy may îlevels or effect of the following drugs (or îside-effects): Zidovudine should be temporarily stopped or dose reduced by 50% on days when cidofovir is administered (probenecid lclearance of zidovudine). Potentially nephrotoxic drugs should be stopped at least 7 days before starting cidofovir, e.g. aminoglycosides, amphotericin, foscarnet, pentamidine, vancomycin or NSAIDs. 			
Action in case of overdose	Monitor renal function. Give prophylactic probenecid and vigorous hydration for 3-7 days.			
Counselling	Men should use barrier contraceptive methods during and for 3 months after			

Risk rating: RED	Note: Risk adjusted to RED - this scoring system does not account for the extra safety requirements for handling this product. Must be prepared in a CIVAS unit.		

Women should not become pregnant during and for 1 month after treatment.

treatment with cidofovir.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Bibliography

SPC Vistide (accessed 9 March 2009).

Ciprofloxacin

2 mg/mL solution in 50-mL, 100-mL, 200-mL infusion bottles

- · Ciprofloxacin lactate is a fluorinated quinolone antibacterial.
- It is active against both Gram-positive and Gram-negative bacteria with particular activity against Gram-negatives: *Salmonella, Shigella, Campylobacter, Neisseria* and *Pseudomonas*.
- Ciprofloxacin is rapidly and well absorbed from the GI tract following oral dosing, so the IV route should be used only when the oral route is unavailable.
- Doses are expressed in terms of the base: Ciprofloxacin 200 mg ≅ 254 mg ciprofloxacin lactate.

Pre-treatment checks

- · Do not give if there is known hypersensitivity to ciprofloxacin or other quinolone antibacterials.
- Use with caution in G6PD deficiency.
- Ciprofloxacin lowers seizure threshold and should be used cautiously in patients with a history of convulsions.
- Patients must be adequately hydrated and asked to drink fluids liberally. Excessive urine alkalinity should be avoided to limit the risk of crystalluria.

Biochemical and other tests

FB	С
LF	Гs

Renal function: U, Cr, CrCl (eGFR)

Dose

Patients must be adequately hydrated and asked to drink fluids liberally.

Standard dose: 200-400 mg twice daily (depending on severity of infection).

Serious infections: in cases of very serious, life-threatening or recurrent infections 400 mg three times daily has been used.

Pseudomonal lower respiratory tract infection in cystic fibrosis: 400 mg twice daily.

Anthrax (treatment and post-exposure prophylaxis): 400 mg twice daily (length of course depends on route of infection).

Urinary tract infections: 100 mg twice daily.

Gonorrhoea: 100 mg as a single dose.

Dose in renal impairment: adjusted according to creatinine clearance:1

- CrCl >20-50 mL/minute: dose as in normal renal function.
- CrCl 10-20 mL/minute: 50-100% of normal dose.
- CrCl <10 mL/minute: 50% of normal dose.

Intermittent intravenous infusion

Preparation and administration

Infusion into a large vein minimises patient discomfort.

- 1. Select the correct size of infusion bottle.
- The infusion is pre-prepared for use. It should be clear and colourless to slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 30 minutes for 200 mg (60 minutes for 400 mg). Infusion into a large vein minimises patient discomfort.

Technical information				
Incompatible with	Sodium bicarbonate. Aminophylline, amoxicillin, amphotericin, ampicillin, ceftazidime, cefuroxime, clindamycin phosphate, co-amoxiclav, dexamethasone sodium phosphate, drotrecogin alfa (activated), flucloxacillin, furosemide, hydrocortisone sodium succinate, magnesium sulfate, methylprednisolone sodium succinate, pantoprazole, phenytoin sodium, propofol, teicoplanin, ticarcillin with clavulanate.			
Compatible with	 Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, Gluc-NaCl, Hartmann's, Ringer's (all with added KCl) Y-site: Amikacin, atracurium, aztreonam, calcium gluconate, cisatracurium, clarithromycin, digoxin, dobutamine, dopamine, fluconazole, gentamicin, granisetron, linezolid, metoclopramide, metronidazole, midazolam, noradrenaline (norepinephrine), ranitidine, remifentanil, tigecycline, tobramycin, verapamil 			
рН	3.5-4.5			
Sodium content	15.4 mmol/100 mL			
Storage	Store below 25°C in original packaging. Do not refrigerate or freeze (crystals may form, which will re-dissolve at room temperature without affecting potency). Use opened vials immediately and discard any unused solution.			

Monitoring

Measure	Frequency	Rationale	
Temperature	Minimum daily	• For clinical signs of fever declining.	
Renal function	Periodically	 If renal function changes, a dose adjustment may be necessary. Urea and creatinine usually increase. The manufacturer recommends twice-weekly creatinine measurement if the patient is on concomitant ciclosporin. 	
FBC		 Eosinophilia is common; leucopenia, neutropenia, anaemia, pancytopenia and thrombocytopenia may also occur. WCC: for signs of the infection resolving. 	
LFT		• ALT, AST, often rise transiently; Alk Phos, GGT and bilirubin rise less commonly.	
Sensitivity testing of infection	Periodically in prolonged therapy	 To ensure that microorganism remains sensitive to therapy. Especially critical with <i>Pseudomonas aeruginosa</i> and <i>Staphylococcus aureus</i>. 	
Blood glucose concentration	↑ frequency in diabetic patients	 Symptomatic hyperglycaemia and/or hypoglycaemia have been reported requiring closer monitoring If signs or symptoms of glucose disturbances develop therapy should be reviewed. 	

(continued)

160 | Ciprofloxacin

Monitoring (continued)				
Measure	Frequency	Rationale		
Signs of CNS disorders	Throughout treatment	 Use with caution in patients with epilepsy or tendency to spasms, previous seizures, vascular disorders in the brain, alterations in brain structure or stroke. If self-destructive behaviour is demonstrated or if seizures occur, discontinue treatment. 		
Signs of tendon damage (including rupture)		 If tendinitis is suspected, discontinue immediately; the affected limb should not be exerted and should be made non-weight-bearing. Most likely in elderly patients or with concomitant corticosteroids. 		
Symptoms of neuropathy		 Due to axonal polyneuropathy and may be irreversible, although incidence is rare. Discontinue if such symptoms occur, e.g. pain, burning, tingling, numbness; or deficits in light touch, pain, temperature, position sense, vibratory sensation, motor strength. 		
Signs of supra- infection or superinfection		 May result in the overgrowth of non-susceptible organisms - appropriate therapy should be commenced; treatment may need to be interrupted. 		
Development of diarrhoea	Throughout and up to 2 months after treatment	 Development of severe, persistent diarrhoea may be suggestive of <i>Clostridium difficile</i>-associated diarrhoea and colitis (pseudomembranous colitis). Discontinue drug and treat. Do not use drugs that inhibit peristalsis. 		

Additional information

Common and serious undesirable effects	Infusion-related: Local: Infusion-site phlebitis. Other: Nausea, diarrhoea, vomiting, abdominal pain; rash, occasionally dizziness and lightheadedness; rarely can cause hypoglycaemia in elderly diabetic patients - monitor blood glucose.
Pharmacokinetics	Elimination half-life is 3-6 hours.
Significant interactions	 Ciprofloxacin may †levels or effect of the following drugs (or †side-effects): agomelatine (avoid combination), artemether with lumefantrine (avoid combination), ciclosporin (†risk of nephrotoxicity), coumarin anticoagulants (monitor INR), duloxetine (avoid combination), NSAIDs (†risk of seizures), theophylline (†risk of seizures; †levels - reduce dose or monitor). Ciprofloxacin may ↓levels or effect of antiepileptic drugs (↓seizure threshold).
Action in case of overdose	Treat symptomatically. Ensure adequate hydration to prevent crystalluria. Monitor renal function.
Counselling	The patient should drink fluids liberally. A rash may develop on exposure to strong sunlight and ultraviolet rays, e.g. sunlamps, solariums - patients should avoid unnecessary exposure.

Risk rating:	GREEN	Score = 0 Lower-risk product: Risk-reduction strategies should be considered.					
The second state of a state full second of a second state of a destate state of a state of a state of a state							

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Bibliography

SPC Ciproxin infusion (accessed 9 March 2009).

Clarithromycin

500-mg dry powder vials

- Clarithromycin is a macrolide antibacterial with a broad, mainly bacteriostatic action against many Gram-positive and, to a lesser extent, some Gram-negative bacteria, as well as some 'atypicals'.
- It is used to treat infections caused by susceptible organisms, e.g. community-acquired pneumonia and skin and soft-tissue infections.

Pre-treatment checks

- · Contraindicated in patients with known hypersensitivity to macrolide antibiotics.
- Avoid in acute porphyria.
- Caution if predisposition to QT interval prolongation (including electrolyte disturbances, concomitant use of drugs that prolong QT interval).

Biochemical and other tests (not all are necessary in an emergency situation)

LFTs	Temperature
Renal function: U, Cr, CrCl (or eGFR)	WCC
Signs of infection	

Dose

Standard dose: 500 mg by IV infusion every 12 hours.

Dose in renal impairment: adjusted according to creatinine clearance:¹

- CrCl >30-50 mL/minute: dose as in normal renal function.
- CrCl 10-30 mL/minute: 250-500 mg every 12 hours.
- CrCl <10 mL/minute: 250–500 mg every 12 hours (vomiting may be a problem).
Intermittent intravenous infusion

Preparation and administration

Clarithromycin must not be given by direct IV or IM injection. Give by IV infusion into a large proximal vein to reduce pain.

- 1. Reconstitute each 500-mg vial with 10 mL WFI.
- Withdraw the required dose and add to a suitable volume of compatible infusion fluid to give a solution containing approximately 2 mg/mL (e.g. add 500 mg to 250 mL NaCl 0.9%).
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion into a large proximal vein over 60 minutes.

Fluid restriction: concentrations up to 5 mg/mL have been given via a central line.

Technical information		
Incompatible with	Aminophylline, ceftazidime, cefuroxime, flucloxacillin, furosemide, heparin sodium, phenytoin sodium.	
Compatible with	Flush: NaCl 0.9% Solutions: Gluc 5% (with added KCl), NaCl 0.9%, Gluc-NaCl, Hartmann's, Ringer's Y-site: Ampicillin, atracurium, benzylpenicillin, bumetanide, cimetidine, ciprofloxacin, co-amoxiclav, dobutamine, dopamine, gentamicin, metoclopramide, metronidazole, ranitidine, ticarcillin with clavulanate, vancomycin, vecuronium bromide, verapamil	
рН	5	
Sodium content	Negligible	
Storage	Store below 30°C in original packaging.	
Displacement value	Negligible	
Stability after preparation	 From a microbiological point of view, should be used immediately; however: Reconstituted vials may be stored at 2-8°C for 24 hours. Prepared infusions (2 mg/mL) may be stored at 2-8°C and infused (at room temperature) within 24 hours. 	
Monitoring		
Measure	Frequency	Rationale
Physical signs of infection	Daily	 Monitor patient response (e.g. FBC, normalisation of observations) for signs of infection resolution - consider review to oral clarithromycin as appropriate.
Injection site	At regular intervals	• Local tenderness and inflammation, phlebitis, pain at the injection site.

(continued)

Monitoring (continued)		
Measure	Frequency	Rationale
Renal function	Weekly	• Dose may need adjusting if renal function changes.
LFTs		 Toxicity - patients should be monitored for elevations of serum hepatic enzymes. Caution required in hepatic impairment. Hepatic dysfunction including cholestatic jaundice has been reported.
Signs of hypersensitivity	Throughout	• In case of hypersensitivity reactions.
Signs of supra-infection or superinfection	iredinieni	 May result in the overgrowth of non-susceptible organisms - appropriate therapy should be commenced; treatment may need to be interrupted.
Development of diarrhoea	Throughout and up to 2 months after treatment	 Development of severe, persistent diarrhoea may be suggestive of <i>Clostridium difficile</i>-associated diarrhoea and colitis (pseudomembranous colitis). Discontinue drug and treat. Do not use drugs that inhibit peristalsis.
Additional inform	nation	
Common and serious undesirable effects	Immediate: Anaphylaxis has been reported rarely. Infusion-related: Local: Pain, thrombophlebitis, extravasation († if administration too rapid). Other: GI disturbances, antibiotic-associated colitis, urticaria, rashes, angioedema, reversible hearing loss after large doses, chest pain, arrhythmias, stomatitis, glossitis	
Pharmacokinetics	Elimination half-life is 3-7 hours (main metabolite: 5-9 hours). Metabolism may become saturated at higher doses.	
Significant interactions	 ↑Risk of ventricular arrhythmias with pimozide (avoid combination). The following may ↑clarithromycin levels or effect (or ↑side-effects): ritonavir (CrCl 30-60 mL/minute the dose of clarithromycin should be ↓by 50%; for CrCl <30 mL/minute the dose of clarithromycin should be ↓ by 75%). Clarithromycin may ↑levels or effect of the following drugs (or ↑side-effects): artemether/lumefantrine (avoid combination), carbamazepine, ciclosporin, cilostazol (avoid combination), clozapine (possible ↑risk of convulsions), colchicine, coumarins (monitor INR), disopyramide, eletriptan (avoid combination), regotamine (avoid combination), methysergide (avoid combination), mizolastine (avoid combination), reboxetine (avoid combination), rifabutin (↑risk of myopathy, avoid combination), sirolimus, tacrolimus, theophylline (monitor levels), verapamil, vinblastine (avoid combination). 	
Action in case of overdose	No known antidote; stop administration and give supportive therapy as appropriate.	
Counselling	Potential for drug interactions; explain short-term alterations in co-prescribing, e.g. withholding statins or theophylline.	

164 | Clarithromycin | Clindamycin

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

Reference

1. Ashley C, Currie A, eds. The Renal Drug Handbook, 3rd edn. Oxford: Radcliffe Medical Press, 2009.

Bibliography

SPC: Klaricid IV, Abbott Laboratories Ltd (accessed 24 October 2007).

Clindamycin

150 mg/mL solution in 2-mL, 4-mL ampoules

- Clindamycin phosphate is a semisynthetic antibiotic that is a derivative of lincomycin (a lincosamide).
- It has primarily bacteriostatic action against Gram-positive aerobes and a wide range of anaerobic bacteria.
- Doses are expressed in terms of the base: Clindamycin 1 g ≅1.2 g clindamycin phosphate.

Pre-treatment checks

- Do not give if there is known hypersensitivity to clindamycin or lincomycin.
- Avoid in acute porphyria and do not give in diarrhoeal states.

Biochemical and other tests

FBC LFTs Renal function: U, Cr, CrCl (or eGFR)

Dose

Serious infections: give every 6–12 hours by IM injection or IV infusion to provide a total daily dose of 600 mg–2.7 g daily.

Life threatening infections: up to 1.2 g by IV infusion every 6 hours.

Dose in renal impairment: dose as in normal renal function. However, prolonged half-life may necessitate dose reduction.¹

Intramuscular injection (maximum dose 600 mg)

Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by deep IM injection.

Intermittent intravenous infusion

Preparation and administration

- 1. Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually 100 mL NaCl 0.9%). The final concentration of the drug should be no more than 18 mg/mL.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion at a **maximum** rate of 30 mg/minute (e.g. 300 mg over 15 minutes; 600 mg over 30 minutes; 900 mg over 45 minutes; 1.2 g over 60 minutes).

Technical information			
Incompatible with	Clindamycin phosphate is incompatible with natural rubber closures. Aminophylline, ampicillin, calcium gluconate, ceftriaxone, ciprofloxacin, doxapram, drotrecogin alfa (activated), fluconazole, magnesium sulfate, phenytoin sodium, ranitidine, tramadol.		
Compatible with	Flush: NaCl 0.9% Solutions: NaCl 0.9%, Gluc 5%, Gluc-NaCl (all including added KCl) Y-site: Aciclovir, amikacin, aztreonam, benzylpenicillin, cefotaxime, ceftazidime, cefuroxime, cisatracurium, esmolol, gentamicin, granisetron, hydrocortisone sodium succinate, labetalol, methylprednisolone sodium succinate, metoclopramide, metronidazole, midazolam, ondansetron, piperacillin with tazobactam, propofol, remifentanil, sodium bicarbonate, tobramycin, verapamil		
рН	5.5-7		
Sodium content	Negligible		
Excipients	Contains benzyl alcohol.		
Storage	Store below 25°C in original packaging. Do not refrigerate or freeze (crystals may form, which will re-dissolve at room temperature without affecting potency).		
Stability after preparation	From a microbiological point of view, should be used immediately; however, prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours.		
Monitoring			
Measure	Frequency	Rationale	
Renal function	Periodically if treatment prolonged	• Manufacturer's recommendation.	
LFTs	neumen proiongeu	 Jaundice and deranged LFTs have occasionally been reported. 	
FBC		• Leucopenia, eosinophilia, and thrombocytopenia have occasionally been reported	

166 | Clindamycin

Monitoring (continued)		
Measure	Frequency Rationale	
Development of diarrhoea	Throughout and up to 3 weeks after treatment	 Development of severe, persistent diarrhoea may be suggestive of <i>Clostridium difficile</i>-associated diarrhoea and colitis (pseudomembranous colitis). Discontinue drug and treat. Do not use drugs that inhibit peristalsis.
Signs of supra-infection or superinfection	Throughout treatment	 May result in the overgrowth of non-susceptible organisms - appropriate therapy should be commenced; treatment may need to be interrupted.
Additional information		
Common and serious undesirable effects	Immediate: Anaphylactoid and other hypersensitivity reactions have been reported. Injection/infusion-related: Local: Pain, induration, abscess after IM injection; thrombophlebitis after IV injection. Other: Diarrhoea (see monitoring above), abdominal discomfort, oesophagitis, oesophageal ulcers, taste disturbances, nausea, vomiting, jaundice, rashes.	
Pharmacokinetics	Elimination half-life is 2-3 hours.	
Significant interactions	 Clindamycin teffect of the following drugs: non-depolarising muscle relaxants, suxamethonium. 	
Action in case of overdose	No known antidote; stop administration and give supportive therapy as appropriate.	
Risk rating: AMBER	Score = 3 Moderate-risk product: Risk-reduction strategies are recommended.	

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Dalacin C Phosphate (accessed 9 March 2009).

# Clodronate sodium (sodium clodronate, disodium clodronate)

#### 60 mg/mL solution in 5-mL ampoules

- Sodium clodronate is a bisphosphonate with properties similar to those of the other bisphosphonates. It inhibits bone resorption but appears to have less effect on bone mineralisation.
- It is used in the treatment of severe ↑Ca associated with malignancy (TIH).
- · Doses are expressed as sodium clodronate.

#### **Pre-treatment checks**

- Do not give to patients already receiving other bisphosphonates.
- Osteonecrosis of the jaw can occur: consider dental examination and preventive dentistry prior to
  planned treatment in patients with risk factors (e.g. cancer, chemotherapy, radiotherapy, corticosteroids, poor oral hygiene). Avoid invasive dental procedures during treatment if possible.
- Give cautiously to patients who have had previous thyroid surgery (increased risk of ↓Ca)
- Contraindicated in pregnancy. Women of child-bearing potential should take contraceptive precautions during *planned* treatment.
- Hydrate patient adequately before, during and after infusions (up to 4 L may be given over 24 hours but over-hydration should be avoided; risk of cardiac failure).

#### Biochemical and other tests

Electrolytes: serum Na, K, Ca, PO<sub>4</sub>, Mg Renal function: U, Cr, CrCl (or eGFR)

#### Dose

The patient must be adequately hydrated using NaCl 0.9% before dosing.

**Tumour-induced hypercalcaemia (TIH):** single infusion of 1500 mg or as multiple infusions of 300 mg daily. The dose given is not dependent on the patient's serum Ca concentration.

- For single infusions, a significant fall in serum Ca is usually seen 24–48 hours after administration and normalisation within 3–7 days. For multiple infusions, these are repeated daily until normocalcaemia is achieved, or for a maximum of 7 days.
- Dose may be repeated in patients not achieving clinically acceptable serum Ca levels by either method. The duration of the response varies.
- Treatment can be repeated whenever ↑Ca recurs. Alternatively, oral treatment may be given daily if appropriate.

Dose in renal impairment: adjusted according to creatinine clearance (see Table C3).

It seems wise to give the dose as smaller multiple infusions – no guidance exists for dose adjustment for large single infusions.

| Creatinine<br>clearance (or eGFR)<br>(mL/minute) | Recommended<br>dose reduction | Recommended<br>daily dose (mg) | Equivalent volume<br>of concentrate (mL) |

#### Table C3 Clodronate sodium dose adjustment in renal impairment

# Single intravenous infusion

Preparation and administration

Clodronate sodium is incompatible with Hartmann's and Ringer's (which contain Ca).

- 1. Withdraw 1500 mg (5  $\times$  5-mL ampoules) and add to 500 mL of either NaCl 0.9% or Gluc 5%.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 4 hours.

#### **Multiple intravenous infusions**

Preparation and administration

Clodronate sodium is incompatible with Hartmann's and Ringer's (which contain Ca).

- 1. Withdraw the required dose and add to 500 mL of either NaCl 0.9% or Gluc 5%.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over at least 2 hours.

| Pharmacokinetics                          | The half-life for elimination from plasma is 2 hours but a second phase with a half-life of 13 hours has been identified (<10% of total urinary excretion takes place during this phase). The substance which is bound to bone is excreted more slowly at a rate corresponding to bone turnover.                                                                                                               |                                                                                                                                                                                                                                                                                           |
| Significant drug<br>interactions          | Clodronate sodium may $\uparrow$ levels or effect (or $\uparrow$ side-effects) of estramustine.                                                                                                                                                                                                                                                                                                                |                                                                                                                                                                                                                                                                                           |

Risk rating: AMBER

Score = 3

Moderate-risk product: Risk-reduction strategies are recommended.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

### Bibliography

SPC Bonefos concentrate (accessed 10/02/09).

# Clonazepam

#### 1 mg/mL solution in ampoules with 1-mL diluent ampoules (WFI)

- · Clonazepam is a benzodiazepine with marked antiepileptic properties.
- It is used for the treatment of epilepsy and myoclonus. By the IV route it has a fast onset of action and may be used in the management of status epilepticus.
- Oral antiepileptic agents should be instituted as soon as the oral route becomes available and is clinically indicated.

#### **Pre-treatment checks**

- Do not use in respiratory depression; acute pulmonary insufficiency; sleep apnoea syndrome; marked neuromuscular respiratory weakness including unstable myasthenia gravis.
- Caution in elderly or debilitated patients, respiratory disease, spinal or cerebellar ataxia; history
  of alcohol or drug abuse, depression or suicidal ideation; avoid sudden withdrawal; myasthenia
  gravis (avoid if unstable); acute porphyria; hepatic impairment; renal impairment; pregnancy and
  breast feeding.
- · Ensure that resuscitation equipment is available.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure LFTs Renal function: U, Cr, CrCl (or eGFR)

#### Dose

Standard dose: 1 mg by slow IV injection or intermittent IV infusion. The dose may be repeated if required.

**Continuous IV infusion:** the BNF advises that IV infusion is potentially hazardous (particularly if prolonged), calling for close and constant observation, and is best carried out in specialist centres with intensive care facilities. Prolonged infusion may lead to accumulation and delayed recovery. **Dose in hepatic impairment**: reduce dose and avoid if severe.

#### Intravenous injection

Preparation and administration

Give slowly into a large vein to reduce risk of thrombophlebitis.

- 1. Withdraw the required dose and dilute with an equal volume of WFI (supplied) to give a concentration of 0.5 mg/mL.
- The solution should be clear and colourless to slightly greenish yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV injection into a large vein of the antecubital fossa at a maximum rate of 0.5 mg/ minute. (There is a risk of thrombophlebitis if smaller veins or faster rates are used.)

## Intermittent intravenous infusion

#### Preparation and administration

- 1. Withdraw the required dose and add to a suitable volume of compatible infusion fluid to give a maximum concentration of 3 mg in 250 mL, e.g. add 1 mg to 100 mL NaCl 0.9%.
- 2. The solution should be clear and colourless to slightly greenish yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion at a maximum rate of 0.5 mg/minute via volumetric infusion device.

### Bibliography

SPC Rivotril ampoules (accessed 14/07/08)

# **Clonidine hydrochloride**

#### 150 micrograms/mL solution in 1-mL ampoules

- · Clonidine hydrochloride acts in the CNS to reduce peripheral resistance, renal vascular resistance, heart rate and BP; it also has effects on spinal alpha2-adrenoceptors.
- · It may be used IV in management of hypertensive crises but has largely been superseded by drugs with an improved side-effect profile.

- Clonidine has been given (unlicensed) by the epidural and intrathecal routes for the management
  of pain.
- It has also been given IV (unlicensed) for the management of severe agitation (often that associated with substance withdrawal) in the critical care setting.

#### **Pre-treatment checks**

- Avoid in patients with severe bradyarrhythmia resulting from either sick sinus syndrome or AV block of second or third degree; unsafe in patients with porphyria.
- Use with caution in patients with cerebrovascular or coronary insufficiency, with a history of depression, Raynaud disease or other peripheral vascular occlusive disease, mild to moderate bradyarrhythmia.

#### Biochemical and other tests

Blood pressure Pulse

#### Dose

**Hypertensive emergency:** 150–300 micrograms by IV injection or infusion. Maximum 750 micrograms in 24 hours. Reduce dose gradually to avoid withdrawal  $\uparrow$ BP.

### Intravenous infusion

#### Preparation and administration

- 1. Withdraw the required dose and add to a suitable volume of NaCl 0.9% (e.g. 50-100 mL).
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 10–15 minutes. Avoid faster administration as this may cause a transient  $\uparrow$ BP.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose. May be diluted to 10 mL with NaCl 0.9% to facilitate slow administration.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV injection over 10–15 minutes. Avoid faster administration as this may cause a transient ↑BP.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# **Bibliography**

CONC

SPC Catapres ampoules 150 micrograms in 1 mL solution for injection (accessed 29 September 2009).

# Co-amoxiclav (amoxicillin sodium-clavulanate)

#### 600-mg and 1.2-g dry powder vials

- Co-amoxiclav is a mixture of the amino penicillin amoxicillin and the beta-lactamase inhibitor clavulanic acid, which synergistically enhances the spectrum of the amoxicillin.
- It should be reserved for bacterial infections likely to be caused by amoxicillin-resistant betalactamase-producing strains.
- Co-amoxiclav doses below are expressed as the combined total mass (mg) of the two constituents: Co-amoxiclav 1.2 g ≡ amoxicillin 1 g (as sodium salt) with clavulanate 200 mg (as potassium salt). Co-amoxiclav doses may also be expressed as individual mass (mg) of amoxicillin/clavulanate.

#### **Pre-treatment checks**

- Do not give if there is known hypersensitivity to penicillins or previous history of penicillinassociated jaundice/hepatic dysfunction.
- · Maintain adequate hydration with high doses.

#### Biochemical and other tests

FBC LFTs Renal function: U, Cr, CrCl (or eGFR)

#### Dose

**Standard dose**: 1.2 g by IV injection or infusion every 8 hours increased to 1.2 g every 6 hours in more serious infections.

**Surgical prophylaxis**: 1.2 g by IV injection at induction and for high-risk procedures (e.g. colorectal surgery); 2–3 further doses of 1.2 g may be given every 8 hours. Check local policies.

Dose in renal impairment: adjusted according to creatinine clearance:<sup>1</sup>

- CrCl >30-50 mL/minute: dose as in normal renal function.
- CrCl 10-30 mL/minute: 1.2 g every 12 hours.
- CrCl <10 mL/minute: 1.2 g every 12 hours or 1.2 g loading dose then 600 mg every 8 hours.

#### Intravenous injection

Preparation and administration

Co-amoxiclav is incompatible with Gluc 5% (but may be injected into drip tubing over 3-4 minutes).

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Add 10 mL WFI to a 600-mg vial (use 20 mL for a 1.2-g vial) then shake vigorously.
- 2. Withdraw the required dose.
- 3. The solution should be clear. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over 3-4 minutes.

## Intermittent intravenous infusion

#### Preparation and administration

Co-amoxiclav is incompatible with Gluc 5%

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Add 10 mL WFI to a 600-mg vial (use 20 mL for a 1.2-g vial) and shake vigorously.
- 2. Withdraw the required dose and add 600 mg to 50 mL NaCl 0.9%; 1.2 g to 100 mL NaCl 0.9%.
- 3. The solution should be clear. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 30-40 minutes.

# **Codeine phosphate**

#### 60 mg/mL solution in 1-mL ampoules

- · Codeine phosphate is an opioid analgesic.
- It is used IM for the treatment of mild to moderate pain. It is much less potent than morphine: 60 mg codeine phosphate IM has the analgesic effect of 5 mg morphine sulfate IM in most individuals.
- Some patients may be ultra-rapid metabolisers of codeine due to a CYP2D6 polymorphism. Rapid
  conversion of codeine to morphine results in higher serum morphine levels and may result in
  toxicity at moderate dosing levels. Conversely, poor metabolisers may not obtain adequate analgesia.
- · Codeine produces less euphoria and sedation than morphine but is still subject to misuse.

#### **Pre-treatment checks**

- Do not use in acute respiratory depression, where there is a risk of paralytic ileus, in raised intracranial pressure and in head injury, in comatose patients and in phaeochromocytoma.
- Caution in JBP, shock, convulsive disorders, supraventricular tachycardias, atrial flutter, chronic
  obstructive pulmonary disease and acute asthma attack, obstructive or inflammatory bowel diseases, biliary tract diseases, alcoholism, prostatic hyperplasia, myasthenia gravis, hypothyroidism
  (reduce dose), adrenocortical insufficiency (reduce dose).
- · Caution in elderly patients use lower doses; initial dose should not exceed 25 mg.
- As codeine reduces peristalsis, increases tone in the bowel and can \cap colonic pressure; it should not be used in diverticulitis, after bowel surgery or in those with acute colitis.
- · Ensure that resuscitation equipment and naloxone are available.

#### Biochemical and other tests

Blood pressure and pulse LFTs Pain score Renal function: U, Cr, CrCl (or eGFR) Respiratory rate

#### Dose

Codeine phosphate should not be given IV: anaphylaxis may occur.

Standard adult dose: 30–60 mg by IM injection every 4 hours when required.
Elderly patients: reduced doses are recommended.
Dose in renal impairment: reduce doses or avoid.
Dose in hepatic impairment: avoid or reduce dose.

#### Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by deep IM injection.

|                                    |                                                                                                                                                                                                                                            |
|                                    |                                                                                                                                                                                                                                            |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

### **Bibliography**

SPC Codeine Phosphate BP injection 60 mg in 1 mL, Martindale Pharma (received 17 April 2009).

# Co-fluampicil (flucloxacillin with ampicillin)

#### 500-mg dry powder vials

- Co-fluampicil is a compound preparation of two penicillins (ampicillin and flucloxacillin) both present as their sodium salts.
- In practice it is used for the treatment of mixed infections, particularly where beta-lactamaseproducing staphylococci are involved or suspected.
- Co-fluampicil doses are expressed below as the combined total mass of the two constituents: Co-fluampicil 500 mg ≡ flucloxacillin 250 mg (as sodium salt) with ampicillin 250 mg (as sodium salt).

#### **Pre-treatment checks**

- Do not give if there is known hypersensitivity to penicillins or beta-lactam antibiotics and to patients with a history of flucloxacillin-associated jaundice/hepatic dysfunction.
- Caution in erythematous rashes common in glandular fever, cytomegalovirus infection, and acute
  or chronic lymphocytic leukaemia.

#### Biochemical and other tests

| Electrolytes: serum Na | LFTs                                  |
|------------------------|---------------------------------------|
| FBC                    | Renal function: U, Cr, CrCl (or eGFR) |

#### Dose

**Standard dose**: 500 mg every 6 hours (may be doubled in severe infections).

**Dose in renal impairment:** There is no guidance on dose reduction in renal impairment, so this product may be unsuitable in these circumstances.

#### Intravenous injection

#### Preparation and administration

See Special handling below.

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Add 10 mL WFI to each vial and shake vigorously.
- 2. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over 3-4 minutes.

#### Intermittent intravenous infusion

#### Preparation and administration

#### See Special handling below.

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Add 10 mL WFI to each vial and shake vigorously.
- Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually 100 mL NaCl 0.9%).
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 30-60 minutes.

#### Intramuscular injection

Preparation and administration

See Special handling below.

- 1. Add 1.5 mL WFI to each vial and shake vigorously.
- 2. Withdraw the required dose.

\_ . . . . .

3. Give by deep IM injection. Rotate injection sites for subsequent injections.

# Colistimethate sodium (colistin sulfomethate sodium)

#### 500 000-unit, 1 million- and 2 million-unit dry powder vials

- · Colistimethate sodium is the anionic form of colistin, a polymyxin antibacterial.
- Because of its toxicity it is used in the treatment of severe Gram-negative infections where there is
  resistance to other antibacterials.
- It may also used by inhalation in the management of respiratory infections, particularly in patients with cystic fibrosis.
- Doses are expressed in international units (IU) in the UK but as milligrams of colistin in the USA: Colistimethate sodium  $1 \text{ mg} \equiv 12500 \text{ units.}$ Colistin base  $1 \text{ mg} \equiv 30000 \text{ units.}$

#### **Pre-treatment checks**

- Do not give if there is known hypersensitivity to colistimethate sodium or to polymyxin B and in patients with myasthenia gravis.
- Caution in acute porphyria.

#### Biochemical and other tests

Renal function: U, Cr, CrCl (or eGFR)

#### Dose

Dosing schedules in the USA differ and the IM route may also be used.

**Bodyweight under 60 kg**: give every 8 hours by IV infusion to provide a total daily dose of 50 000–75 000 units/kg.

**Bodyweight over 60 kg:** 1–2 million units every 8 hours by IV infusion up to a maximum of 6 million units in 24 hours.

**Dose in renal impairment**: dose is adjusted according to CrCl and then further adjusted according to blood levels and evidence of toxicity. Doses here are for bodyweight >60 kg.

- CrCl >20–50 mL/minute: dose as in normal renal function.
- CrCl 10-20 mL/minute: 1 million units every 12-18 hours.
- CrCl <10 mL/minute: 1 million units every 18-24 hours.

Nebulisation: 1-2 million units twice daily.

#### Intermittent intravenous infusion (preferred route)

#### Preparation and administration

- 1. Reconstitute each vial with 10 mL WFI or NaCl 0.9%. The vial should be gently swirled to avoid frothing.
- Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually 100 mL NaCl 0.9%).
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 30 minutes.

# Intravenous injection (in patients with a totally implantable venous access device [TIVAD] only)

#### Preparation and administration

- 1. Reconstitute each vial with 10 mL WFI or NaCl 0.9%. The vial should be gently swirled to avoid frothing.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Withdraw the required dose and give by IV injection over a minimum of 5 minutes.

### **Nebulisation**

#### Preparation and administration

Nebulisation should take place in a well-ventilated room; the output from the nebuliser should be vented to the open air or a filter may be fitted.

- 1. Dissolve the powder for the required dose in 2-4 mL NaCl 0.9% or WFI.
- 2. The solution will be slightly hazy and may froth if shaken.
- 3. Give by nebuliser: a jet or ultrasonic nebuliser is preferred.

# Additional information

| Common and serious<br>undesirable effects | Immediate: Hypersensitivity reactions have been reported, including rash<br>Injection/infusion-related: Local: Injection-site reactions.<br>Other: Neurotoxicity (especially at high doses), nephrotoxicity. Inhalation<br>may cause sore throat, sore mouth, cough, bronchospasm.                                                                                                                   |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pharmacokinetics                          | Elimination half-life is 2-3 hours (2 hours in cystic fibrosis).                                                                                                                                                                                                                                                                                                                                     |
| Significant<br>interactions               | <ul> <li>Colistimethate may flevels or effect of the following drugs (or fside-effects): ciclosporin (frisk of nephrotoxicity), diuretics-loop (frisk of ototoxicity), muscle relaxants-non depolarising, platinum compounds (frisk of nephrotoxicity and ototoxicity), suxamethonium.</li> <li>Colistimethate may ilevels or effect of the following drugs: neostigmine, pyridostigmine.</li> </ul> |
| Action in case of<br>overdose             | No specific antidote; manage by supportive treatment. Overdose can result in<br>neuromuscular blockade leading to muscular weakness, apnoea, possible<br>respiratory arrest; also acute renal failure.                                                                                                                                                                                               |
| Counselling                               | Patients using nebulised solutions at home should be advised to administer them immediately after reconstitution.                                                                                                                                                                                                                                                                                    |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

#### **Bibliography**

SPC Colomycin injection (accessed 10 March 2009).

SPC Promixin 1 MIU powder for solution for injection (accessed 10 March 2009). SPC Promixin 1 MIU powder for nebuliser solution (accessed 10 March 2009).

# Co-trimoxazole (trimethoprim-sulfamethoxazole)

#### 96 mg/mL solution in 5-mL ampoules

- Co-trimoxazole contains a 5:1 ratio of sulfamethoxazole to trimethoprim (i.e. 80 mg: 16 mg/mL), each of which act synergistically at different points of the folate metabolic pathway.
- Its main use IV is in the management of Pneumocystis pneumonia, toxoplasmosis and nocardiasis.
- Because of the risk of serious side-effects, co-trimoxazole should only be considered for other infections where there is good bacteriological evidence of sensitivity to co-trimoxazole and good reason to prefer this combination to a single antibacterial.
- Doses in this monograph are expressed in terms of the total combined mass (mg) of the two constituents. (Doses in the USA are usually expressed in terms of the trimethoprim component.)

#### **Pre-treatment checks**

- Do not give if there is known hypersensitivity to sulfonamides, trimethoprim, co-trimoxazole or any of the excipients and in acute porphyria.
- Use with caution in asthma and G6PD-deficiency.

#### Biochemical and other tests

Electrolytes: serum K, NaLFTsFBC including folateRenal function: U, Cr, CrCl (or eGFR)

#### Dose

Standard dose: 960 mg (10 mL) by IV infusion every 12 hours.

Severe infections: 1.44 g (15 mL) by IV infusion every 12 hours.

**Treatment of** *Pneumocystis jiroveci (P. carinii)* infections: give every 6–12 hours by IV infusion to provide a total daily dose of 120 mg/kg. Switch to oral dosing (at the same dose) as soon as possible. Treat for 14–21 days.

Dose in renal impairment: adjusted according to creatinine clearance:

- CrCl >30-50 mL/minute: dose as in normal renal function.
- CrCl 15-30 mL/minute: 480 mg every 12 hours.
- CrCl <15 mL/minute: not recommended unless haemodialysis facilities are available.

#### Intermittent intravenous infusion

#### Preparation and administration

concentration of

sulfamethoxazole

2-3 days in renal

impairment

- 1. Withdraw the required dose and add to a suitable volume of compatible infusion fluid (NaCl 0.9% or Gluc 5%). Manufacturer recommends that 5 mL be added to 125 mL; 10 mL to 250 mL; 15 mL to 500 mL.\*
- 2. Shake thoroughly then visually inspect for turbidity or crystallisation and discard if present.
- 3. Give by IV infusion over 90 minutes. If turbidity or crystallisation develops during the infusion the mixture should be discarded.

\*An alternative source reports doses <40 mL being added to 500 mL Gluc 5% and doses >40 mL being added to 1 L NaCl 0.9%. The resultant mixture is given by IV infusion over 90–120 minutes and observed closely for signs of turbidity.<sup>1</sup>

**Fluid restriction**: add each 5-mL ampoule to 75 mL Gluc 5% and give by IV infusion over no more than 60 minutes.

|---------------------------------------------------------------------------------|
| methotrexate (†haematological toxicity), phenytoin (monitor levels, †antifolate |
| effect), pyrimethamine (↑antifolate effect).                                    |
|                                                                                 |

Co-trimoxazole may ↓levels or effect of ciclosporin.

Action overd  Injectable preparation contains ethanol and propylene glycol; may interact with disulfiram and metronidazole.

| Symptoms to watch for: Nausea, vomiting, dizziness and confusion. |
|-------------------------------------------------------------------|
| Antidote: No known antidote but haemodialysis may be effective.   |
| Stop administration and give supportive therapy as appropriate.   |
|                                                                   |

Counselling The development of rash, sore throat, fever, pallor, arthralgia, cough, shortness of breath, purpura, or jaundice may be an early sign of a serious adverse reaction.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Cyanocobalamin (vitamin B<sub>12</sub>)

#### 1 mg/mL solution in ampoules

- Vitamin B<sub>12</sub>, a water-soluble vitamin, occurs in the body in various forms including cyanocobalamin. Deficiency may occur in strict vegetarians, in patients with malabsorption syndromes or metabolic disorders, or in patients following gastrectomy or extensive ileal resection. Deficiency results in megaloblastic anaemias, demyelination and other neurological damage.
- Cyanocobalamin is no longer the vitamin B<sub>12</sub> form of choice for therapy as hydroxocobalamin is retained in the body for longer and maintenance therapy therefore involves less frequent administration.
- Vitamin B<sub>12</sub> preparations are used to treat pernicious anaemia, for prophylaxis and treatment of other macrocytic anaemias associated with vitamin B<sub>12</sub> deficiency. Only hydroxocobalamin is used to treat tobacco amblyopia and Leber's optic atrophy (use of cyanocobalamin may allow these optic atrophies to degenerate further).
- Hydroxocobalamin or cyanocobalamin may be used diagnostically as part of the Schilling test to
  assess absorption of vitamin B<sub>12</sub> if absence of intrinsic factor is suspected.

#### **Pre-treatment checks**

- Do not use for the treatment of megaloblastic anaemia of pregnancy unless a definite diagnosis of vitamin B<sub>12</sub> deficiency has been established.
- · Contraindicated in Leber disease and tobacco amblyopia.

#### Biochemical and other tests

Electrolytes: serum K (cardiac arrhythmias secondary to  $\downarrow$ K during initial therapy have been reported – correct if necessary).

FBC.

Folate (to ensure that folate deficiency is not a contributory/causative factor).

A baseline assessment of neurological function is useful to assess impact of treatment in cases of vitamin B<sub>12</sub> deficiency anaemia with neurological complications.

#### Dose

The IV route is not recommended as most of the dose is lost in the urine.

#### Pernicious anaemia and other macrocytic anaemias without neurological involvement:

initially 250–1000 micrograms by IM injection on alternate days for 1–2 weeks then 250 micrograms once weekly until the blood count has normalised, then 1 mg monthly.

**Pernicious anaemia and other macrocytic anaemias with neurological involvement:** initially 1 mg by IM injection on alternate days as long as improvement is occurring then 1 mg monthly.

**Prophylaxis of macrocytic anaemias associated with vitamin B<sub>12</sub> deficiency:** 250 micrograms-1 mg monthly.

**Schilling test**: involves use of IM vitamin B<sub>12</sub> as part of the test.

#### Intramuscular injection

Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

# Cyclizine

#### 50 mg/mL solution in 1-mL ampoules

- · Cyclizine lactate is an antihistamine with antimuscarinic activity and mild sedative effects.
- It is used as an antiemetic in the management of nausea and vomiting including postoperatively and after radiotherapy (especially for breast cancer since cyclizine does not *prolactin levels*). It may also be used to treat vomiting and attacks of vertigo associated with Ménière's disease and other vestibular disturbances.
- At lower doses cyclizine increases the lower oesophageal sphincter tone, thereby reducing the risk
  of regurgitation and aspiration.
- Cyclizine lactate may also be given (unlicensed) by SC infusion in palliative care to treat nausea and vomiting.
- Doses of parenteral cyclizine lactate are similar to cyclizine hydrochloride doses given orally.

#### **Pre-treatment checks**

- Caution in patients with glaucoma, obstructive disease of the GI tract, hepatic disease, severe heart failure, epilepsy and males who may have prostatic hypertrophy.
- Avoid in patients with porphyria.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure LFTs

#### Dose

**Prevention and treatment of nausea and vomiting**: 50 mg up to three times a day by IM or IV injection.

**Preoperatively in patients undergoing emergency surgery**: 25 mg by IV injection to reduce risk of aspiration of gastric contents during induction of general anaesthesia.

**Prevention of postoperative nausea and vomiting (PONV)**: administer first dose of cyclizine by slow IV injection 20 minutes before the anticipated end of surgery.

#### Intramuscular injection

Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose. It may be diluted with an equal volume of WFI to facilitate slow administration.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 3-5 minutes.

### 194 | Cyclizine

# Bibliography

SPC Valoid (accessed 7 July 2008).

# **Dalteparin sodium**

10 000 units/mL solution in 1-mL ampoules and 1-mL graduated pre-filled syringes 12 500 units/mL solution in 0.2-mL pre-filled syringes

25000 units/mL solution in 0.2-mL, 0.3-mL, 0.4-mL, 0.5-mL, 0.6-mL and 0.72-mL prefilled syringes

#### 25000 units/mL solution in 4-mL multidose vials

- Dalteparin sodium is an antithrombotic low-molecular-weight heparin (LMWH).
- It is used in the prophylaxis and treatment of VTE including the extended treatment of patients
  with solid tumours, the treatment of ACS and also for the prevention of thrombus formation in the
  extracorporeal circulation during haemodialysis.
- · Not all preparations are licensed for all indications.
- Doses are expressed in terms of international anti-Factor Xa activity units: Dalteparin sodium 1 mg ≅ 110–210 units of anti-Factor Xa activity.

#### **Pre-treatment checks**

- Avoid in acute bacterial endocarditis, major bleeding or high risk of uncontrolled haemorrhage including recent haemorrhagic stroke.
- Dalteparin in treatment dosage is contraindicated in patients undergoing locoregional anaesthesia in elective surgical procedures.
- Placement or removal of a spinal/epidural catheter should be delayed for 10–12 hours after administration of prophylactic doses, whereas patients receiving higher doses (1.5 mg/kg once daily) require a 24 hours delay. Subsequent doses should be given no sooner than 4 hours after catheter removal.
- · Caution with other drugs affecting haemostasis, such as aspirin or clopidogrel.
- · Use with extreme caution in patients with a history of HIT.
- Patients with severe renal or hepatic impairment may need a reduced dose (or at least closer monitoring of ADRs).

#### Biochemical and other tests (not all are necessary in an emergency situation)

Bodyweight (in certain indications) Electrolytes: serum K LFTs Platelet count Renal function: U, Cr, CrCl (or eGFR)

#### Dose

#### Prophylaxis

**General surgery with moderate risk of VTE:** 2500 units by SC injection 1–2 hours before the procedure and thereafter 2500 units by SC injection once daily until the patient is mobile.

**General surgery with high risk of VTE:** 5000 units by SC injection the evening before the surgical procedure and 5000 units on subsequent evenings. Alternatively, 2500 units by SC injection 1–2 hours before the procedure followed by 2500 units by SC injection after 8–12 hours. Thereafter give 5000 units by SC injection once daily until mobile.

**Prolonged thromboprophylaxis in hip replacement surgery:** 5000 units by SC injection the evening before the surgical procedure and 5000 units on subsequent evenings. Dosing may be continued for up to 5 weeks after hip replacement surgery.

Medical patients (high risk of VTE): 5z000 units by SC injection once daily.

#### Prevention of extracorporeal thrombus formation during haemodialysis:

- For dialysis sessions <4 hours give 5000 units by IV injection at the start of dialysis.
- For dialysis sessions >4 hours give 30-40 units/kg by IV injection at the start of dialysis followed by 10-15 units/kg/hour by IV infusion. In patients at high risk of bleeding or in acute renal failure give 5-10 units/kg by IV injection followed by 4-5 units/kg/hour by IV infusion.

#### Treatment

Treatment of VTE: give by SC injection once daily based on bodyweight as indicated in Table D1 (approximately 200 units/kg). Treat for at least 5 days and until INR > 2.

In patients at high risk of bleeding, give 100 units/kg by SC injection twice daily. Ampoules or multidose vials may be used to facilitate dosing.

#### Table D1 Treatment of VTE and treatment for the first 30 days of cancer-related VTE

| Bodyweight (kg) | Syringe to use         |
|-----------------|------------------------|
| <46             | 7500 units (0.3 mL)    |
| 46-56           | 10 000 units (0.4 mL)  |
| 57-68           | 12 500 units (0.5 mL)  |
| 69-82           | 15 000 units (0.6 mL)  |
| ≥83             | 18 000 units (0.72 mL) |

Cancer-related VTE: give by SC injection once daily based on bodyweight as indicated in Table D1 (approximately 200 units/kg) for the first 30 days. Then give by SC injection once daily based on bodyweight as indicated in Table D2 (approximately 150 units/kg) for a further 5 months or longer depending on individual risk.

See product literature for dose in chemotherapy-induced thrombocytopenia.

Treatment of ACS: give 120 units/kg by SC injection every 12 hours (maximum 10000 units every 12 hours) for up to 8 days until clinically stable. See Table D3.

If treatment is required beyond 8 days, reduce the dose to either 5000 units (women <80 kg, men <70 kg) or 7500 units (women  $\ge$ 80 kg, men  $\ge$ 70 kg) every 12 hours for no more than 45 days.

 Table D3
 Treatment of ACS (for up to 8 days)

Dose in renal impairment: adjusted according to creatinine clearance:<sup>1</sup>

- CrCl >20-50 mL/minute: dose as in normal renal function.
- CrCl 10–20 mL/minute: dose as in normal renal function for prophylaxis only. For treatment doses either monitor anti-Factor Xa levels or use unfractionated heparin.
- CrCl <10 mL/minute: dose as in normal renal function for prophylaxis only. For treatment doses either monitor anti-Factor Xa levels or use unfractionated heparin.

Dose in hepatic impairment: the manufacturer advises to avoid in severe hepatic impairment.

# **Subcutaneous injection**

#### Preparation and administration

- 1. Select the correct pre-filled syringe. Pre-filled syringes are ready for immediate use; do not expel the air bubble. If necessary expel any excess dalteparin to give the required dose.
- 2. If using multidose vials or ampoules, withdraw the required dose using a needle suitable for SC administration.
- 3. The patient should be seated or lying down.
- 4. Pinch up a skin fold on the abdominal wall between the thumb and forefinger and hold throughout the injection.
- Give by deep SC injection into the thick part of the skin fold at right angles to the skin. Do not rub the injection site after administration. Alternate doses between the right and left sides.

# Intravenous injection (haemodialysis only)

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless to pale straw in colour. Inspect visually for particulate matter or discoloration prior to administration.
- 3. Give as a rapid IV injection.

# Intravenous infusion via a syringe pump (haemodialysis only)

#### Preparation and administration

- 1. Withdraw the required dose and make up to a suitable volume with NaCl 0.9% or Gluc 5% for administration via syringe pump.
- 2. Cap the syringe and mix well.
- 3. The solution should be clear and colourless to pale straw in colour. Inspect visually for particulate matter or discoloration prior to administration.
- 4. Give by IV infusion at the prescribed rate via a syringe pump.

#### **Technical information** Incompatible with No information Flush: NaCl 0.9% Compatible with Solutions: NaCl 0.9%, Gluc 5% Y-site: No information 5-7.5 pН Sodium content Negligible Excipients Multidose vials contain benzyl alcohol. Storage Pre-filled syringes: store below 25°C. Multidose vials and ampoules: store below 30°C. In use: Vials should be stored below 30°C and contents used within 14 days of first use. Stability after From a microbiological point of view, prepared infusions should be used preparation immediately; however, the preparation is known to be stable at room temperature for up to 24 hours.

# Monitoring

# **Danaparoid sodium**

#### 750 anti-Factor Xa units/0.6 mL solution in ampoules

- · Danaparoid sodium is a low-molecular-weight heparinoid with actions similar to heparin.
- Provided there is no evidence of cross-reactivity, danaparoid may be used in the treatment of VTE in patients who have previously had, or who develop, HIT.
- It may be also be used for the prevention of VTE in patients undergoing general or orthopaedic surgery.
- Doses are expressed in terms of international anti-Factor Xa activity units: Danaparoid 1 mL ≈ 1250 units of anti-Factor Xa activity.

# **Pre-treatment checks**

- There are a number of contraindications:
  - Treatment of DVT: do not use locoregional anaesthesia in surgical procedures.
  - Severe haemorrhagic diathesis, e.g. haemophilia and idiopathic thrombocytopenic purpura, unless the patient also has HIT and no alternative antithrombotic treatment is available.
  - · Haemorrhagic stroke in the acute phase.
  - Uncontrollable active bleeding state.
  - Severe renal and/or hepatic insufficiency, unless the patient also has HIT and no alternative antithrombotic treatment is available.
  - · Severe uncontrolled hypertension.
  - · Active gastroduodenal ulcer, unless it is the reason for operation.
  - Diabetic retinopathy.
  - Acute bacterial endocarditis.
  - A positive in-vitro aggregation test for the heparin-induced antibody in the presence of danaparoid in patients with a history of HIT.
  - · Hypersensitivity to sulfites.
- Use with caution in moderate impairment of renal and/or hepatic function.

#### Biochemical and other tests

#### Bodyweight

Plasma cross-reactivity in plasma for patients with history of HIT (if test is available) Renal function: U, Cr, CrCl (or eGFR)

# Dose

#### Prophylaxis

**VTE prophylaxis in general or orthopaedic surgery:** 750 anti-Factor Xa units (0.6 mL) by SC injection twice daily until the patient is mobile. Danaparoid should be started preoperatively; the last preoperative dose being given a minimum of 1–4 hours before surgery.

#### Treatment

Treatment of VTE in HIT: an initial dose is given by IV injection based on bodyweight:

- <55 kg: 1250 anti-Factor Xa units (1 mL).
- 55–90 kg: 2500 anti-Factor Xa units (2 mL).
- >90 kg: 3750 anti-Factor Xa units (3 mL).

This is followed by an IV infusion given at a rate of 400 units/hour for 2 hours, then 300 units/hour for 2 hours, then a maintenance infusion of 200 units/hour for 5 days.

Dose in renal impairment: adjusted according to creatinine clearance:<sup>1</sup>

- CrCl >20-50 mL/minute: dose as in normal renal function.
- CrCl 10-20 mL/minute: use with caution.
- CrCl <10 mL/minute: use with caution. Reduce second and subsequent doses for VTE prophylaxis.

Dose in hepatic impairment: use with caution in moderate hepatic impairment.

# **Subcutaneous injection**

# Preparation and administration

- 1. Withdraw the required dose.
- 2. The patient should be seated or lying down.
- 3. Pinch up a skin fold on the abdominal wall between the thumb and forefinger and hold throughout the injection.
- 4. Give by deep SC injection into the thick part of the skin fold at right angles to the skin. Do not rub the injection site after administration. Alternate doses between the right and left sides.

# **Intravenous injection**

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by rapid IV injection.

# Intravenous infusion via a syringe pump

Preparation of a 200 anti-Factor Xa units/mL infusion with a total volume of 22.5 mL (other concentrations and volumes may be used)

- 1. Withdraw 4500 units (3.6 mL  $\equiv 6 \times 0.6$  mL ampoules) of danaparoid injection solution into a syringe.
- 2. Withdraw 18.9 mL of compatible diluent into a 30-mL syringe.
- 3. Add the danaparoid injection to the diluent, cap the syringe, and mix well.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

- 1. Give by IV infusion via syringe pump at 2 mL/hour for 2 hours, then 1.5 mL/hour for 2 hours then continue at 1 mL/hour.
- 2. Prepare a fresh syringe at least every 24 hours.

| Action in case of overdose                                                             | Supportive therapy as appropriate. Protamine sulfate only partially neutralises the anticoagulant effect of danaparoid and cannot be relied on to reverse bleeding associated with overdosage.                                                                                                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |  |
| Counselling                                                                            | Report bleeding episodes.<br>Report any signs of neurological impairment with concurrent spinal<br>anaesthesia.                                                                                                                                                                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |  |

#### 204 | Danaparoid sodium | Dantrolene sodium

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Dantrolene sodium

#### 20-mg dry powder vials

- Dantrolene sodium is a muscle relaxant acting directly on skeletal muscle, thus reducing muscle contractility in response to excitation.
- It is used IV to treat malignant hyperthermia. It has also been used in the USA both orally and IV to
  pretreat individuals prior to surgery who are at risk of developing malignant hyperthermia.

#### **Pre-treatment checks**

As soon as the malignant hyperthermia syndrome is recognised, stop all anaesthetic agents.

#### Biochemical and other tests (not all are necessary in an emergency situation)

#### Bodyweight

LFTs - do not give to patients with active liver disease

#### Dose

**Malignant hyperthermia:** 1 mg/kg given by rapid IV injection. Repeat as necessary up to a cumulative maximum of 10 mg/kg. Clinical experience has shown that the average dose required is 2.5 mg/kg. The manufacturers note that a 70-kg man may require approximately 36 vials (to give 10 mg/kg) and that such a volume could be administered in approximately  $1^{1}$ /<sub>2</sub> hours.

**Prophylaxis of malignant hyperthermia (unlicensed):** in the USA, pretreatment with either 1–2 mg/kg orally four times daily for 1–2 days prior to surgery or 2.5 mg/kg by IV infusion over 60 minutes starting approximately 75 minutes before anaesthesia. Further doses are given during anaesthesia if signs of malignant hyperthermia develop.

# Intravenous injection

#### Preparation and administration

Dantrolene sodium is incompatible with NaCl 0.9%, Gluc 5%. Use of a central line is preferable if possible because of the high pH.

- 1. Add 60 mL WFI to each 20-mg vial and shake the vial until the solution is clear. The resultant solution contains dantrolene sodium 0.333 mg/mL.
- 2. Withdraw the required dose.
- The solution should be clear and colourless to orange. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by rapid IV injection. Use of a central line is preferable if possible because of the high pH.

#### Intermittent intravenous infusion

Preparation and administration

Dantrolene sodium is incompatible with NaCl 0.9%, Gluc 5%. Use of a central line is preferable if possible because of the high pH.

- 1. Add 60 mL WFI to vial and shake the vial until the solution is clear. The resultant solution contains dantrolene sodium 0.333 mg/mL.
- Transfer the required volume of reconstituted solution into an appropriate sized empty sterile IV plastic bag for administration.
- The solution should be clear and colourless to orange. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 60 minutes. Use of a central line is preferable because of the high pH.

| Action in case of overdose                | Stop administration and give supportive therapy as appropriate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                               |

#### Risk rating: RED

 $\mathsf{Score} = \mathsf{7}$ 

High-risk product: Risk-reduction strategies are required to minimise these risks.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# **Bibliography**

SPC Dantrium (accessed 20 January 2009).

# Daptomycin

#### 350-mg, 500-mg dry powder vials

- Daptomycin is a cyclic lipopeptide antibacterial.
- It is used to treat complicated skin and soft-tissue infections (cSSTI) caused by resistant Grampositive bacteria, and right-sided infective endocarditis (RIE) due to *Staphylococcus aureus*.

# **Pre-treatment checks**

Culture and sensitivity confirmation if used for RIE.

#### Biochemical tests

| Bodyweight | LFTs                                  |
|------------|---------------------------------------|
| CK         | Renal function: U, Cr, CrCl (or eGFR) |
| FBC        |                                       |

#### Dose

**cSSTI without concurrent** *S. aureus* **bacteraemia:** 4 mg/kg once every 24 hours for 7–14 days or until the infection is resolved.

**cSSTI with concurrent** *S. aureus* **bacteraemia:** 6 mg/kg once every 24 hours in accordance with the perceived risk of complications in the patient (duration may be longer than 14 days).

**Known or suspected RIE due to** *S. aureus*: 6 mg/kg once every 24 hours. The duration is determined by whichever official guideline is being followed.

Dose in renal impairment: adjusted according to creatinine clearance:1

- CrCl 30-50 mL/minute: dose as in normal renal function.
- CrCl <30 mL/minute: 4 mg/kg every 48 hours.

**Dose in hepatic impairment**: no dose adjustment necessary in mild to moderate impairment (Child–Pugh Class A or B) but insufficient experience is available with Child–Pugh Class C, therefore caution should be exercised.

# Intermittent intravenous infusion

Preparation and administration

Daptomycin is incompatible with Gluc solutions.

- 1. Reconstitute each 350-mg vial with 7 mL NaCl 0.9% (use 10 mL for each 500-mg vial). Inject through the rubber stopper and aim at the wall of the vial.
- 2. Gently rotate to fully wet the powder then leave to stand for 10 minutes.
- 3. Gently swirl the vial (do not shake) for a few minutes until a clear solution has developed. The reconstituted solution contains 50 mg/mL.
- 4. The solution should be clear and yellow to light brown. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Invert the vial to allow the solution to drain towards the stopper. Withdraw the required dose by slowly pulling the syringe plunger all the way to end of the syringe to remove the entire vial contents.
- Expel air, large bubbles and any excess solution to obtain the required dose and add to a suitable volume of NaCl 0.9% (usually 50 mL).
- 7. Give by IV infusion over 30 minutes.

#### Intravenous injection

Preparation and administration

Daptomycin is incompatible with Gluc solutions.

- 1. Reconstitute each 350-mg vial with 7 mL NaCl 0.9% (use 10 mL for each 500-mg vial). Inject through the rubber stopper and aim at the wall of the vial.
- 2. Gently rotate to fully wet the powder then leave to stand for 10 minutes.
- 3. Gently swirl the vial (do not shake) for a few minutes until a clear solution has developed. The reconstituted solution contains 50 mg/mL.

- 4. The solution should be clear and yellow to light brown. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Invert the vial to allow the solution to drain towards the stopper. Withdraw the required dose by slowly pulling the syringe plunger all the way to end of the syringe to remove the entire vial contents.
- 6. Expel air, large bubbles and any excess solution to obtain the required dose.
- 7. Give by IV injection over 2 minutes.

# Desferrioxamine mesilate (desferoxamine mesylate)

#### 500-mg or 2-g dry powder vials

- Desferrioxamine is a chelating agent that has a high affinity for ferric iron. When given by
  injection it forms a stable water-soluble iron-complex (ferrioxamine) that can be excreted in the
  urine and in bile. It can also chelate aluminium.
- It increases the excretion of iron from the body and is used in acute iron poisoning and also in conditions associated with chronic iron overload such as iron storage disorders and in conditions requiring repeated blood transfusions.
- As desferrioxamine can also chelate aluminium, it has also been used to reduce aluminium overload in patients with end-stage renal failure on maintenance dialysis. However, it may exacerbate aluminium-related encephalopathy and precipitate seizures.
- Theoretically 100 mg desferrioxamine could chelate 8.5 mg of ferric iron, and 4.1 mg of aluminium.

#### **Pre-treatment checks**

- Not recommended for use in pregnancy or lactation, and has been found to be teratogenic in animal studies (especially in the first trimester). The risks and benefits of treatment should be assessed before considering chelation therapy in pregnancy or lactation.
- Check that the patient does not have a history of desferrioxamine mesilate intolerance before administration.

#### Biochemical and other tests

#### Baseline audiological review.

Baseline neurological assessment in patients with aluminium-related encephalopathy.

Baseline ophthalmic assessment (visual field measurements, funduscopy, colour vision testing using pseudoisochromatic plates and the Farnsworth D-15 colour test, slit lamp investigation and visual evoked potential studies).

Baseline U&Es (may require dose adjustment in renal impairment; treatment of aluminium overload may result in  $\downarrow$ Ca).

Bodyweight.

Coma and shock indicate severe poisoning. Urgent treatment is required. Death may occur at this stage.

Serum aluminium level (in diagnosis and treatment of aluminium overload in end-stage renal failure).

Serum ferritin (in chronic iron overload).

Serum iron taken at about 4 hours after ingestion is the best laboratory measure of severity of overdose:

<3 mg/L (55 micromol/L) – mild toxicity 3–5 mg/L (55–90 micromol/L) – moderate toxicity

>5 mg/L (90 micromol/L) - severe toxicity.

#### Dose

It is essential to consult a poisons information service, e.g. Toxbase at www.toxbase.org (password or registration required) for full details of the management of acute iron toxicity.

Acute iron poisoning (in addition to other supportive measures as appropriate): 15 mg/ kg/hour by continuous IV infusion, reduced after 4–6 hours. Maximum dose is usually 80 mg/kg in 24 hours.

Alternatively, if IV infusion is not possible, give 2 g by IM injection as a single dose. (In the USA, 1 g is given by IM injection followed by 500 mg at intervals of 4–12 hours up to a maximum of 6 g daily depending on clinical response.)

**Chronic iron overload:** usually 20–60 mg/kg/day by SC infusion 3–7 times per week. 24-hour urinary iron excretion should be monitored daily initially. Higher doses should only be used if likely benefit outweighs risks. Desferrioxamine may also be given by IV infusion during blood transfusion. **Diagnosis of iron storage disease and certain anaemias:** 500 mg by IM injection. Urine is then collected for 6 hours and its iron content is determined. Excretion of 1–1.5 mg (18–27 micromoles) of iron is suggestive of iron overload; values >1.5 mg (27 micromoles) can be regarded as pathological. **Diagnosis of aluminium overload in end-stage renal failure:** recommended in patients with serum aluminium levels >60 nanograms/mL associated with serum ferritin levels >100 nanograms/mL associated with serum ferritin levels >100 nanograms/mL associated in mediately before haemodialysis. During the last 60 minutes of the haemodialysis session, desferrioxamine 5 mg/kg is given by slow IV infusion. Before the next haemodialysis session a second blood sample is taken. An increase in serum aluminium above baseline of >150 nanograms/mL is suggestive of aluminium overload; a negative test does not eliminate the possibility of aluminium overload.

**Treatment of aluminium overload in end-stage renal failure:** indicated if the patient is symptomatic owing to organ impairment, or if aluminium level is consistently >60 nanograms/ mL associated with a positive desferrioxamine test (see above). Usual dose in all patients is 5 mg/kg once weekly. This is given by IV infusion in haemodialysis/haemofiltration, or by the intraperitoneal route, IM injection, SC infusion or IV infusion in CAPD or CCPD patients. Regimens are dependent on test results – see product literature for details.

**Dose in renal impairment:** dose as in normal renal function but elimination of chelated metals may be impaired in severe renal impairment – haemodialysis is advised.

# **Continuous intravenous infusion**

Used for acute iron poisoning and where SC infusions are not feasible in chronic conditions.

#### Preparation and administration

- 1. Dissolve each 500-mg vial in 5 mL WFI (or 2-g vial in 20 mL WFI) to make a 10% solution (100 mg/mL).
- 2. Withdraw the required dose and add to a convenient volume of NaCl 0.9% or Gluc 5%. Mix well.
- The solution should be clear and pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion at a rate not exceeding 15 mg/kg/hour reducing to 5 mg/kg/hour as soon as there is clinical improvement.
- 5. Care should be taken when flushing the line to avoid the sudden infusion of residual desferrioxamine which may be present in the dead space of the line, as this may lead to flushing, LBP and acute collapse.
- 6. 24-hour urinary iron excretion should be measured regularly where intensive IV chelation is required, and the dose adjusted accordingly.

# **Subcutaneous infusion**

#### Preparation and administration

- 1. Dissolve each 500-mg vial in 5 mL WFI (or 2-g vial in 20 mL WFI) to make a 10% solution (100 mg/mL).
- Withdraw the required dose into a suitable syringe. This may then be further diluted with a convenient volume of NaCl 0.9% or Gluc 5%.
- Give by SC infusion over 8–12 hours taking care not to insert the needle too close to the dermis. It
  may be possible to further ↑iron excretion by infusing the same daily dose over a 24-hour period.

# Intraperitoneal administration

#### Preparation and administration

- 1. Dissolve each 500-mg vial in 5 mL WFI to make a 10% solution (100 mg/mL).
- 2. Withdraw the required dose and add to an appropriate volume of dialysis fluid.
- 3. The solution should be clear and pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give intraperitoneally whilst patient is on CAPD or CCPD usually prior to last exchange of the day.

# Intramuscular injection (relatively ineffective -- use only when SC infusion are not feasible)

#### Preparation and administration

- 1. Dissolve each 500-mg vial in 5 mL WFI (or 2-g vial in 20 mL WFI) to make a 10% solution.
- 2. Withdraw the required dose.
- 3. Give by IM injection.

# **Desmopressin acetate (DDAVP)**

#### 4 micrograms/mL solution in 1-mL ampoules

- Desmopressin is a synthetic analogue of vasopressin. It has greater antidiuretic activity and a more
  prolonged action than vasopressin. It also stimulates factor VIII and plasminogen activator activity
  in the blood, but has little pressor activity. In its injectable form it is used:
  - To diagnose cranial diabetes insipidus; assess renal concentration capacity; to test for fibrinolytic response.
  - To treat cranial diabetes insipidus; to increase Factor VIII:C and Factor VIII:Ag in patients with mild to moderate haemophilia or von Willebrand disease undergoing surgery or following trauma; to treat headache resulting from lumbar puncture.
- Doses are expressed in terms of desmopressin acetate: Desmopressin acetate 1 microgram ≅ desmopressin 0.903 microgram.

#### **Pre-treatment checks**

- Do not use in habitual and psychogenic polydipsia.
- Caution in hypertension, heart disease, cardiac insufficiency and other conditions requiring treatment with diuretic agents.
- · Desmopressin does not reduce prolonged bleeding time in thrombocytopenia.

#### Diagnostic testing

• When used for diagnostic purposes, fluid intake must be limited to that required to satisfy thirst, and must not exceed 500 mL from 1 hour before until 8 hours after administration.

#### Haemostatic use

- Do not give in unstable angina pectoris, decompensated cardiac insufficiency or von Willebrand disease Type IIB (where administration may result in pseudo thrombocytopenia).
- For haemophilia and von Willebrand disease, if the patient has not previously received desmopressin treatment, assay Factor VIII levels prior to the start of treatment.

#### Biochemical and other tests

Bodyweight (in some indications) Baseline blood pressure and pulse Baseline plasma osmolarity *or* baseline bodyweight (to enable monitoring of fluid balance) Electrolytes: Serum Na, K

#### Dose

#### For existing diabetes insipidus patients switched from maintenance to parenteral dosing:

- Intranasal 10 micrograms ≅ parenteral 1 microgram.
- Oral 100 micrograms ≅ parenteral 1 microgram.

**Treatment of cranial diabetes insipidus:** 1–4 micrograms once daily by SC or IM injection or IV infusion (see above for conversion from other routes).

**Diagnosis of cranial diabetes insipidus:** 2 micrograms by SC or IM injection. Limit fluid intake (see above). Failure to produce concentrated urine after water deprivation, followed by the ability to do so after the administration of desmopressin, confirms a diagnosis of cranial diabetes insipidus. Failure to concentrate after the administration suggests nephrogenic diabetes insipidus.

# 216 | Desmopressin acetate

**Renal function testing:** 2 micrograms by SC or IM injection should elicit urine concentrations > 700 mOsmol/kg in the period of 5–9 hours following the dose. The bladder should be emptied at the time the dose is given. Limit fluid intake (see above).

**Fibrinolytic response testing:** 0.4 micrograms/kg bodyweight by IV infusion. Take a venous blood sample 20 minutes after the infusion. In patients with a normal response the sample should show fibrinolytic activity of euglobulin clot precipitate on fibrin plates of  $\geq$ 240 mm<sup>2</sup>.

Mild to moderate haemophilia and von Willebrand disease: 0.4 micrograms/kg bodyweight by IV infusion. Give the dose immediately prior to surgery or following trauma.

If results from a previous administration of desmopressin are not available then take blood pre-dose and 20 minutes post-dose for assay of Factor VIII levels. The increase in Factor VIII levels is dependent on basal levels and is normally 2–5 times the pre-treatment levels.

Give further doses every 12 hours for as long as cover is required. Continue to monitor Factor VIII levels as some patients have shown a diminishing response to successive doses.

For surgical patients, unless contraindicated, give tranexamic acid orally from 24 hours beforehand until healing is complete.

**Post lumbar puncture headache due to dural puncture:** 4 micrograms by SC or IM injection. Repeat after 24 hours if necessary. Alternatively, 4 micrograms can be given prophylactically immediately prior to lumbar puncture and 24 hours later.

# **Subcutaneous injection**

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by SC injection.

# Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

#### Intravenous infusion

#### Preparation and administration

- 1. Withdraw the required dose and add to 50 mL NaCl 0.9%.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 20 minutes.

| Significant<br>interactions   | No significant interactions.                                                                                                                        |
| Action in case of<br>overdose | Symptoms to watch for: ↑Risk of water retention and/or ↓Na i.e. water intoxication. Restrict fluid intake and manage symptomatically.               |
| Counselling                   | For diagnostic tests, limit fluid intake to a maximum of 500 mL from 1 hour before until 8 hours after administration.                              |

#### 218 | Desmopressin acetate | Dexamethasone

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC DDAVP/Desmopressin injection (accessed 3 February 09).

# Dexamethasone

#### 4 mg/mL solution in 1-mL ampoules and 2-mL vials; 24 mg/mL solution in 5-mL vials

- · Dexamethasone sodium phosphate is a corticosteroid with mainly glucocorticoid activity.
- It is used in the treatment of conditions for which systemic corticosteroid therapy is indicated (except adrenal-deficiency states). Its virtual lack of mineralocorticoid properties makes it particularly suitable for treating conditions in which water retention would be a disadvantage such as cerebral oedema associated with cerebral neoplasm.
- It is used parenterally when a rapid effect is required in emergencies, e.g. cerebral oedema, and also
  when the oral route is temporarily unavailable or inappropriate.
- It may also be given by intra-articular, intrasynovial, intralesional or soft-tissue injection for various inflammatory conditions.
- Doses below are expressed in terms of dexamethasone phosphate: Dexamethasone phosphate 1 mg ≅ 1.1 mg dexamethasone sodium phosphate.
   NB: Some manufacturers state the strength of their products in terms of dexamethasone: Dexamethasone 3.3 mg ≡ 4 mg dexamethasone phosphate ≡ 4.3 mg dexamethasone sodium phosphate.

#### **Pre-treatment checks**

- Avoid where systemic infection is present (unless specific therapy given).
- · Avoid live virus vaccines in those receiving immunosuppressive doses.
- May activate or exacerbate amoebiasis or strongyloidiasis (exclude before initiating a corticosteroid in those at risk or with suggestive symptoms). Fungal or viral ocular infections may also be exacerbated.
- Caution in patients predisposed to psychiatric reactions, including those who have previously suffered corticosteroid-induced psychosis, or who have a personal or family history of psychiatric disorders.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Bodyweight in certain indications Electrolytes: serum Na, K

#### Dose

**Standard dose:** 0.5–24 mg daily by IM or IV injection/infusion; doses vary depending on the condition being treated.

**Cerebral oedema associated with malignancy:** initially 10 mg by IV injection followed by 4 mg IM every 6 hours as required for 2–4 days. This should be gradually reduced and stopped or an oral maintenance dose may be necessary. Much higher doses are also licensed for use in acute life-threatening cerebral oedema.

**Adjunctive treatment of bacterial meningitis (unlicensed):** 10 mg by IV injection every 6 hours for 4 days (starting before or with first dose of antibacterial treatment).

#### Intra-articular, intrasynovial or soft-tissue injection:

- Large joints: 2–4 mg; small joints: 0.8–1 mg; bursas: 2–3 mg; tendon sheaths: 0.4–1 mg; soft tissue infiltration: 2–6 mg; ganglia: 1–2 mg.
- Injections may be repeated every 3-5 days (e.g. for bursas) or every 2-3 weeks (for joints).

# Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over a minimum of 3 minutes (may be diluted with NaCl 0.9% or Gluc 5% to facilitate slow administration.)

#### Intermittent intravenous infusion

#### Preparation and administration

- 1. Withdraw the required dose and add to 100 mL of compatible infusion fluid (usually NaCl 0.9%).
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 15 minutes.

### Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by deep IM injection into the gluteal muscle.

# **Other routes**

#### Preparation and administration

- 1. Withdraw the required dose
- 2. Inject into the affected area.
  - In tenosynovitis care should be taken to inject into the tendon sheath rather than into the substance of the tendon.
  - After intra-articular injections treatment failure is usually the result of not entering the joint space.

# Dexrazoxane

#### 500-mg dry powder vials

- Dexrazoxane hydrochloride is a cytoprotective agent which is hydrolysed to an active metabolite that chelates iron within cells.
- It is used (as Cardioxane) to reduce the cardiotoxicity of doxorubicin and other anthracyclines. It
  actively chelates iron within cells, thus preventing the formation of the anthracycline-iron
  complex that is thought to cause cardiotoxicity.
- It is also use (as Savene) in the management of anthracycline extravasation, where its action is to inhibit the enzyme topoisomerase II.

# **Pre-treatment checks**

Biochemical and other tests (not all are necessary in an emergency situation)

| Baseline ECG      | FBC                                   |
|-------------------|---------------------------------------|
| Baseline LVEF     | LFTs                                  |
| Body surface area | Renal function: U, Cr, CrCl (or eGFR) |

#### Dose

**Prevention of anthracycline-induced cardiotoxicity (Cardioxane):** the dose is calculated by multiplying the doxorubicin-equivalent dose by 20 or the epirubicin-equivalent dose by 10 (e.g. a dose of  $1000 \text{ mg/m}^2$  dexrazoxane is given when doxorubicin is given at a dose of  $50 \text{ mg/m}^2$  or epirubicin is given at a dose of  $100 \text{ mg/m}^2$ ).

In the USA, the doxorubicin dose is multiplied by 10 and the manufacturer recommends that initiation is delayed until patients have received a cumulative doxorubicin hydrochloride dose of 300 mg/m<sup>2</sup> as one study suggested potential interference with antineoplastic efficacy.

**Anthracycline extravasation (Savene):** days 1 and 2:  $1000 \text{ mg/m}^2$ ; day 3:  $500 \text{ mg/m}^2$ . For a body surface area of  $>2 \text{ m}^2$  a single dose should not exceed 2000 mg.

The first infusion should be initiated as soon as possible and within the first 6 hours after extravasation. Treatment on the remaining days should start at the same hour as on the first day. If there is a chance of extravasation by drugs other than anthracyclines through the same IV access (e.g. vincristine, mitomycin, vinorelbine) then Savene will **not** be effective for these drugs.

**Dose in renal impairment:** in patients with creatinine clearance <40 mL/minute the Cardioxane dose should be reduced by 50%. There is no experience of such reduced doses in the treatment of extravasation therefore use of Savene in renal impairment is not recommended.

**Dose in hepatic impairment:** the dosage ratio for Cardioxane remains the same. Savene has not been studied in patients with hepatic impairment.

#### Intermittent intravenous infusion (Cardioxane)

See Special handling below.

#### Preparation and administration

- Dissolve the contents of each vial in 25 mL WFI. This may take a few minutes with gentle shaking. If the colour immediately on reconstitution is **not** colourless to yellow, discard.
- Withdraw the required dose and further dilute each 500 mg with 25–100 mL of Hartmann's (larger volumes are preferred as the infused solution is then less acidic).

- 3. The solution should be clear and colourless to yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 15 minutes approximately 30 minutes prior to anthracycline dose.

# Intermittent intravenous infusion (Savene)

See Special handling below.

#### Preparation and administration

- 1. Remove cooling measures such as ice packs from the affected area at least 15 minutes before administration to allow sufficient blood flow.
- 2. Reconstitute each vial with 25 mL WFI to give a concentration of 20 mg/mL. The reconstituted solution is slightly yellow.
- 3. Withdraw the required dose of dexrazoxane and add to the 500 mL of the Savene diluent provided.
- 4. The solution should be clear and colourless to yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by IV infusion over 1–2 hours into a large vein in an area other than the one affected by the extravasation.

| Incompatible with              | No information, but do not mix dexrazoxane with other drugs during infusion.                                                                                                                                                                                     |  |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|

# **Dextran 70**

#### Dextran 70 6% in NaCl 7.5% solution in 250-mL infusion bag

- Dextran 70 is a colloidal plasma substitute that contains large molecules that do not readily leave the intravascular space, where they exert osmotic pressure to maintain circulatory volume. It exerts a colloidal osmotic pressure similar to that of plasma proteins and in comparison with crystalloids, smaller volumes are required to produce the same expansion of blood volume.
- It is used in the initial treatment of hypovolaemia with ↓BP induced by traumatic injury (after primary stabilisation of respiration and bleeding).

# Pre-treatment checks (not all are necessary in an emergency situation)

As this product is often used in acute, emergency settings, e.g. ambulance crews attending stab victims, it is probable that these pre-treatment checks will not be feasible in most instances.

 Caution in those patients likely to develop circulatory overload such as congestive cardiac failure, renal failure and pulmonary oedema.

#### 226 | Dextran 70

- Caution also in those patients at risk of liver disease and bleeding disorders (NB: the amount of dextran 70 contained in a 250-mL dose is not likely to affect haemostasis, since changes in haemostatic variables only occur at doses above 1.5 g/kg bodyweight. Aggressive fluid resuscitation can, however, dilute blood clotting factors to such an extent that a bleeding diathesis occurs).
- Hypertonic solutions should be used with caution in patients with diabetes mellitus having severe hyperglycaemia with hyperosmolality.

Biochemical and other tests (not all are necessary in an emergency situation)

| Blood pressure            | Hydration status      |
|---------------------------|-----------------------|
| Electrolytes: serum Na, K | Renal function: U, Cr |
| FBC                       |                       |

#### Dose

**Initial treatment of hypovolaemia with hypotension induced by traumatic injury**: 250 mL followed immediately by the administration of appropriate isotonic replacement fluids, dosed according to the needs of the patient.

# Intravenous infusion

#### Preparation and administration

- 1. The infusion is pre-prepared for use. It should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 2. Give the full dose by rapid IV infusion over 2–5 minutes.
- 3. Discard any unused portion. Do not reconnect partially used infusion containers.
- 4. Follow immediately by the administration of appropriate isotonic replacement fluids.

# Diamorphine hydrochloride (diacetylmorphine hydrochloride, heroin)

#### 5-mg and 10-mg dry powder in ampoules

- Diamorphine hydrochloride is a potent opioid analgesic. It is more potent than morphine with a
  faster onset and shorter duration of action. It is also more water-soluble, which is useful in
  palliative care as high doses can be given in a relatively small volume.
- It is used parenterally for the treatment of severe acute pain and may also be used to relieve dyspnoea in acute pulmonary oedema.
- · Diamorphine may also be given by SC infusion in to control pain in palliative care.

#### **Pre-treatment checks**

- Do not use in acute respiratory depression, where there is a risk of paralytic ileus, in raised intracranial pressure and in head injury, in comatose patients, in acute abdomen, in delayed gastric emptying, in chronic constipation, in cor pulmonale, in acute porphyria and in phaeochromocytoma.
- Caution in LBP, shock, convulsive disorders, supraventricular tachycardias, atrial flutter, chronic
  obstructive pulmonary disease and acute asthma attack, obstructive or inflammatory bowel diseases, biliary tract diseases, alcoholism, prostatic hyperplasia, myasthenia gravis, hypothyroidism
  (reduce dose), adrenocortical insufficiency (reduce dose).
- · Caution in toxic psychosis, pancreatitis, severe diarrhoea and CNS depression.
- Ensure that resuscitation equipment and naloxone are available especially for IV administration.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure and pulse Pain score Renal function: U, Cr, CrCl (or eGFR) Respiratory rate

#### Dose

Doses above those stated must not be given to opioid naive patients.

**Acute pain:** 5 mg by SC or IM injection or 1.25-2.5 mg by slow IV injection every 4 hours when required (dose may be increased up to 10 mg for heavier patients with †muscle mass).

**Chronic pain:** 5–10 mg by SC or IM injection regularly every 4 hours adjusted according to requirements. Initial dose is dependent on previous opioid exposure.

**Myocardial infarction:** 5 mg by slow IV injection, then a further 2.5–5 mg if required. Halve the dose in elderly or frail patients.

Acute pulmonary oedema: 2.5-5 mg by slow IV injection.

Dose in renal impairment: reduce dose or avoid.

Dose in hepatic impairment: reduce dose or avoid.

#### **Subcutaneous injection**

Preparation and administration

Check that you have selected the correct strength of ampoule. High-strength ampoules, i.e. 30-mg, 100-mg and 500-mg, are available for use in palliative care. These are not suitable for use in acute situations.

- 1. Reconstitute the ampoule with 1 mL WFI.
- 2. Withdraw the required dose.
- 3. Give by SC injection.
- Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving the initial dose, especially elderly patients or those of low bodyweight.

#### Intramuscular injection

Preparation and administration

Check that you have selected the correct strength of ampoule. High-strength ampoules, i.e. 30-mg, 100-mg and 500-mg, are available for use in palliative care. These are not suitable for use in acute situations.

- 1. Reconstitute the ampoule with 1 mL WFI.
- 2. Withdraw the required dose.
- 3. Give by IM injection.
- 4. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving the initial dose, especially elderly patients or those of low bodyweight.

#### Intravenous injection

#### Preparation and administration

Check that you have selected the correct strength of ampoule. High-strength ampoules, i.e. 30-mg, 100-mg and 500-mg, are available for use in palliative care. These are not suitable for use in acute situations.

- 1. Reconstitute the ampoule with 1 mL WFI.
- 2. Withdraw the required dose. It may be further diluted with NaCl 0.9% or Gluc 5% to facilitate slow administration.

#### 230 | Diamorphine hydrochloride

- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by slow IV injection at a maximum rate of 1 mg/minute.
- 5. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving the initial dose, especially elderly patients or those of low bodyweight.

# **Diazepam emulsion**

#### 5 mg/mL emulsion in 2-mL ampoules

Diazepam emulsion contains diazepam dissolved in the oil phase of an oil in water emulsion and should not be confused with diazepam solution (see the Diazepam solution monograph).

- Diazepam is a long-acting benzodiazepine with anxiolytic, anticonvulsant and central muscle relaxant properties.
- Diazepam emulsion is used to provide sedation prior to procedures such as endoscopy, as a premedication before general anaesthesia, to control acute muscle spasms (e.g. from poisoning) or convulsions (status epilepticus) and to manage severe acute anxiety or agitation.

#### 232 | Diazepam emulsion

#### **Pre-treatment checks**

- · Avoid in acute porphyria or respiratory depression.
- Caution in patients with pulmonary insufficiency or myasthenia gravis.
- Caution in patients with impaired renal and hepatic function (avoid in severe hepatic impairment).

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Bodyweight | Renal function: U, Cr, CrCl (or eGFR) |
|------------|---------------------------------------|
| LFTs       | Respiratory rate                      |

#### Dose

Sedation prior to minor surgical or dental procedures: 100–200 micrograms/kg by IV injection. Usual adult dose 10–20 mg.

Premedication: 100-200 micrograms/kg by IV injection.

**Status epilepticus and convulsions due to poisoning:** 10 mg by slow IV injection, repeated if necessary after 10 minutes. Once the seizure is controlled, recurrence may be prevented by a slow IV infusion (maximum total dose 3 mg/kg over 24 hours). Reduce dose on prolonged use to  $\downarrow$ risk of accumulation and CNS depression.

Severe acute anxiety, acute muscle spasm (including tetanus) and acute states of excitement, delirium tremens: 10 mg by IV injection repeated after 4 hours if necessary.

#### Intravenous injection

#### Preparation and administration

Diazepam emulsion is incompatible with NaCl 0.9% (but may be injected into drip tubing containing NaCl 0.9%).

- 1. Withdraw the required dose.
- The preparation is a milky white emulsion. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV injection (maximum rate 5 mg/minute) into a large vein to avoid thrombosis.

# **Continuous intravenous infusion**

Preparation and administration

Diazepam emulsion is incompatible with NaCl 0.9%.

- 1. Withdraw the required dose (bearing in mind that the prepared infusion is only stable for a maximum of 6 hours).
- Add to a suitable volume of compatible infusion fluid (usually Gluc 5%) to give a final concentration in the range 100–400 micrograms/mL (i.e. 2–8 mL of diazepam emulsion per 100 mL). Mix well.
- 3. The preparation is a milky white emulsion. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion via a volumetric infusion device or syringe pump at an appropriate rate.
- 5. Prepare a fresh infusion at least every 6 hours if required.

### **Bibliography**

SPC Diazemuls (accessed 21 May 2008).

# **Diazepam solution**

monograph. These may not all be applicable in some clinical situations.

#### 5 mg/mL solution in 2-mL ampoules

Diazepam solution contains diazepam dissolved in an aqueous medium and should not be confused with diazepam emulsion (see the Diazepam emulsion monograph).

- Diazepam is a long-acting benzodiazepine with anxiolytic, anticonvulsant and central muscle relaxant properties.
- It is used parenterally to provide sedation prior to procedures such as endoscopy, to control acute muscle spasms (e.g. from poisoning) or convulsions (status epilepticus) and to manage severe acute anxiety or agitation.

#### **Pre-treatment checks**

- Avoid in acute porphyria, respiratory depression.
- Caution in patients with pulmonary insufficiency or myasthenia gravis.
- Caution in patients with impaired renal and hepatic function (avoid in severe hepatic impairment).

### Biochemical and other tests (not all are necessary in an emergency situation)

| Bodyweight | Renal function: U, Cr, CrCl (or eGFR) |
|------------|---------------------------------------|
| LFTs       | Respiratory rate                      |

#### Dose

Sedation prior to minor surgical or dental procedures: 100-200 micrograms/kg by IV injection. Usual adult dose 10-20 mg.

**Status epilepticus and convulsions due to poisoning:** 10 mg by slow IV injection, repeated if necessary after 10 minutes. Once the seizure is controlled, recurrence may be prevented by a slow IV infusion (maximum total dose 3 mg/kg over 24 hours). Reduce the dose on prolonged use to *\prisk* of accumulation and CNS depression.

Severe acute anxiety, acute muscle spasm (including tetanus) and acute states of excitement, delirium tremens: 10 mg by IV injection repeated after 4 hours if necessary.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV injection (maximum rate 5 mg/minute) into a large vein to avoid thrombosis.

#### Intramuscular injection (use only if oral or IV route not possible)

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

#### **Continuous intravenous infusion**

**Not recommended.** Diazepam emulsion (see separate monograph) is the preferred preparation for IV infusion because it forms a more stable preparation and is also less irritant to veins. It can therefore be given in more concentrated infusion solutions, thus facilitating the administration of higher doses.

PVC containers and giving sets should not be used – more than 50% of the dose may be adsorbed. Glass or polyethylene should be used in preference.

#### Preparation and administration

- 1. Withdraw the required dose of diazepam solution (bearing in mind that stability data are limited and that several shorter infusions would be better than a single 24-hour infusion).
- 2. Add each 10 mg to at least 200 mL NaCl 0.9% or Gluc 5%. Mix well.
- 3. The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by continuous IV infusion via a volumetric infusion device.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# **Bibliography**

SPC Diazepam 5 mg/mL solution for injection, Wockhardt UK Ltd (accessed 21 May 2008).

# Diazoxide

#### 15 mg/mL solution in 20-mL ampoules

- Diazoxide is a benzothiadizine analogue and is related structurally to the thiazide diuretics.
- · It has been used in the management of hypertensive emergencies when first-line drugs such as sodium nitroprusside or hydralazine are ineffective or unsuitable. Adverse effects are pronounced and the BNF identifies the drug as less suitable for use.
- IV injection produces a prompt reduction in BP by relaxing smooth muscle in the peripheral arterioles. Cardiac output is increased as BP is reduced; coronary and cerebral blood flow are maintained. Renal blood flow is increased after an initial decrease.

#### **Pre-treatment checks**

- Diazoxide is not recommended for use in *fBP* due to mechanical abnormality, e.g. aortic coarctation or AV shunt.
- · Caution in patients in whom retention of Na and water or abrupt reductions in BP may be hazardous, e.g. those with impaired cardiac or cerebral circulation.

#### Biochemical and other tests

| Bodyweight     | Electrolytes: serum Na                |
|----------------|---------------------------------------|
| Blood pressure | Renal function: U, Cr, CrCl (or eGFR) |

#### Dose

**Standard dose:** 1–3 mg/kg by rapid IV injection up to a maximum single dose of 150 mg; may be repeated after 5–15 minutes if required. Repeated administration at 4–24 hour intervals is generally sufficient to maintain BP below pre-treatment levels. Oral antihypertensive agents should replace therapy as soon as adequate BP control has been achieved.

Dose in renal impairment: use with caution if CrCl <10 mL/minute.

### Intravenous injection

See Spillage precautions below.

Preparation and administration

- 1. Withdraw the required dose.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. The patient should be lying down.
- 4. Give by rapid IV injection over no more than 30 seconds (slow administration reduces the antihypertensive response). Use a cannula for administration, taking care to avoid extravasation.
- 5. Patients should remain supine during, immediately following and, preferably, for at least 1 hour after IV dosing.

| Technical information     |                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |  |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

### Bibliography

SPC Eudemine injection (accessed 20 April 2010).

# **Diclofenac sodium**

#### 25 mg/mL solution in 3-mL ampoules; 37.5 mg/mL solution in 2-mL ampoules (Dyloject)

There are different formulations of diclofenac injectable: not all products are licensed for all indications or all routes (check product literature).

- · Diclofenac sodium is a non-steroidal anti-inflammatory drug (NSAID).
- The injection form is used to treat acute pain and for treatment or prevention of postoperative pain. Maximum duration of parenteral treatment is 48 hours; oral or rectal therapy should be instituted as soon as possible if necessary.
- Parenteral administration gives rise to a 2-fold increase in bioavailability compared with oral and rectal administration as it avoids first-pass metabolism; the active substance is 99.7% protein bound.

#### **Pre-treatment checks**

- Avoid in patients with active peptic ulceration, history of recurrent ulceration, or GI bleeding or perforation related to previous NSAID therapy, patients with severe heart failure, patients who have had asthma induced by aspirin or other NSAIDs, nasal polyps, angioedema or urticaria.
- Do not give to patients with severe hepatic or renal failure.
- · In addition if using the IV route do not give:
  - If the patient is already taking a NSAID or anticoagulant (including low-dose heparin).
  - If the patient has a history of haemorrhagic diathesis, a history of confirmed or suspected cerebrovascular bleeding.
  - · In operations associated with a high risk of haemorrhage.
  - When there is a history of asthma.
  - In moderate or severe renal impairment (serum creatinine >160 micromol/L).
  - In hypovolaemia or dehydration from any cause.

Biochemical and other tests (not all are necessary in an emergency situation)

| Blood | pressure |  |
|-------|----------|--|
| FBC   |          |  |

LFTs Renal function: U, Cr, CrCl (or eGFR)

#### Dose

The total daily dose of diclofenac is 150 mg by any route.

For acute exacerbations of pain and postoperative pain: 75 mg by IM injection once daily (twice daily in severe pain) for a maximum of 48 hours.

For renal colic: 75 mg by IM injection repeated once after 30 minutes if required.

#### IV use in acute postoperative pain:

- Voltarol and Goldshield preparations (IV injection only): 75 mg by IV infusion over 30–120 minutes, repeated after 4–6 hours if necessary to a maximum dose of 150 mg in 24 hours. Alternatively, give 25–50 mg by IV infusion over 15–60 minutes followed by a continuous IV infusion of 5 mg/hour up to a maximum dose of 150 mg in 24 hours.
- Dyloject (IV injection only): 75 mg by IV injection, repeated after 4–6 hours if necessary to a
  maximum dose of 150 mg in 24 hours. Alternatively, give 25–50 mg by IV injection followed by
  additional IV injections up to a maximum dose of 150 mg in 24 hours.

Dose in renal impairment: adjusted according to creatinine clearance:1

- CrCl >20-50 mL/minute: dose as in normal renal function.
- CrCl 10-20 mL/minute: dose as in normal renal function but avoid if possible.
- CrCl <10 mL/minute: dose as in normal renal function but only use if end-stage renal failure on dialysis.

### Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by deep IM injection into the upper outer quadrant of the gluteal muscle, taking care to avoid the sciatic nerve and also inadvertent SC injection. If a second injection is required, use the alternate buttock.

### Intermittent or continuous intravenous infusion

For dilution of Voltarol and Goldshield products, NaCl 0.9% or Gluc 5% must be buffered with sodium bicarbonate before use (see below). Dyloject is not licensed for use by IV infusion.

#### Preparation and administration

- 1. Select an infusion bag containing 100–500 mL of NaCl 0.9% or Gluc 5% and add 0.5 mL sodium bicarbonate 8.4% or 1 mL sodium bicarbonate 4.2% to buffer the solution. Mix well.
- 2. Withdraw the required dose of diclofenac and add to the previously buffered infusion fluid. Mix well.
- The solution should be clear and colourless to faintly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 30-120 minutes or continuously depending upon indication.

# Intravenous injection

Dyloject brand only.

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 5-60 seconds.

# Dicobalt edetate (cobalt edetate, cobalt EDTA)

#### 300 mg/20 mL (1.5%) solution in 20-mL ampoules

• Dicobalt edetate is a specific antidote for cyanide poisoning. Its use arises from the property of cobalt salts to form a relatively non-toxic stable ion-complex with cyanide.

Dicobalt edetate is toxic and potentially fatal in the absence of cyanide poisoning. Use only if poisoning is confirmed and is moderate to severe (see below). It should only be given when the patient is tending to lose, or has lost, consciousness. It must never be used as a precautionary measure.

#### **Pre-treatment checks**

- Must only be used in cases of confirmed severe cyanide poisoning. There is a reciprocal antidote
  action between cyanide and cobalt. Thus in the absence of cyanide, dicobalt edetate injection itself
  is toxic. If the patient is fully conscious, it is unlikely that the extent of poisoning warrants the use
  of dicobalt edetate injection.
- It is important to be aware whether any cyanide antidote therapy has been given in the prehospital setting since repeat doses of some antidotes can cause serious side-effects.

Biochemical and other tests

Nil

# Doses of cyanide poisoning antidotes<sup>1</sup> (see relevant entries)

It is essential to consult a poisons information service, e.g. Toxbase at www.toxbase.org (password or registration required) for full details of the management of cyanide toxicity.

Mild poisoning (nausea, dizziness, drowsiness, hyperventilation, anxiety):

- Observe.
- Give 12.5 g sodium thiosulfate (50 mL of 25% or 25 mL of 50% solution) IV over 10 minutes.

**Moderate poisoning** (reduced conscious level, vomiting, convulsions,  $\downarrow$ BP): as well as other supportive measures:

If dicobalt edetate is available:

- Give 300 mg (20 mL) of 1.5% dicobalt edetate solution IV over 1 minute.
- Follow immediately with 50 mL Gluc 50%.

If dicobalt edetate is not available:

• Give 12.5 g sodium thiosulfate (50 mL of 25% or 25 mL of 50% solution) IV over 10 minutes.

**Severe poisoning** (coma, fixed dilated pupils, cardiovascular collapse, respiratory failure, cyanosis): *If dicobalt edetate is available:* 

As well as other supportive measures:

- Give 300 mg (20 mL) of 1.5% dicobalt edetate solution IV over 1 minute.
- Follow immediately with 50 mL Gluc 50%.
- If there is only a partial response to dicobalt edetate 300 mg, or the patient relapses after recovery, give a further dose of dicobalt edetate 300 mg. If a second dose of dicobalt edetate is given, there is ↑risk of cobalt toxicity but only if the diagnosis is not cyanide poisoning.

If dicobalt edetate is not available:

As well as other supportive measures:

- Give 300 mg (10 mL) of 3% sodium nitrite solution IV over 5–20 minutes.
- Follow with 12.5 g sodium thiosulfate (50 mL of 25% or 25 mL of 50% solution) IV over 10 minutes.
- A further dose of sodium thiosulfate 12.5 g IV over 10 minutes may then be given.
- A second dose of sodium nitrite should **not** be given because of the risk of excessive methaemoglobinaemia.

### **Intravenous injection**

- 1. Withdraw the required dose.
- The solution should be clear and rose-violet coloured. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 1 minute.
- 4. Administer Gluc 50% and sodium thiosulfate as specified above.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Digoxin

#### 250 micrograms/mL solution in 2-mL ampoules

- Digoxin is a cardiac glycoside which increases force of myocardial contraction and reduces conduction through the AV node.
- It is used to treat cardiac failure and is used in the management of supraventricular arrhythmias, particularly chronic atrial flutter and fibrillation.
- The IV route may be used to administer an emergency loading dose in atrial fibrillation or flutter but often oral loading is effective.
- It may also be given IV where the enteral route is temporarily unavailable.

#### **Pre-treatment checks**

- Avoid in intermittent complete heart block, second-degree AV block; supraventricular arrhythmias associated with accessory conducting pathways, e.g. Wolff–Parkinson–White syndrome; ventricular tachycardia or fibrillation; hypertrophic cardiomyopathy (unless concomitant atrial fibrillation and heart failure – but with caution).
- Avoid if LK or LMg (risk of digoxin toxicity). A reduction in serum potassium concentration from 3.5 to 3.0 mmol/L is accompanied by an increase in sensitivity to digoxin of about 50% and digoxin toxicity may be present despite the serum digoxin concentration being in the apparent therapeutic range.<sup>1</sup>
- · Caution following recent MI; sick sinus syndrome; thyroid disease and pregnancy.
- · Reduce the dose in elderly patients and in renal impairment.
- · Withhold for 24 hours before elective cardioversion.

Biochemical and other tests (not all are necessary in an emergency situation)

| Electrolytes: serum K | Renal function: U, Cr, CrCl (or eGFR) |
|-----------------------|---------------------------------------|
| Heart rate            | TFTs                                  |

#### Dose

The IM and SC routes should not be used because absorption is erratic and pain and tissue damage are problematic.

**Emergency loading dose for atrial fibrillation or flutter:** 0.75–1 mg by IV infusion over at least 2 hours. The dose may alternatively be given in divided doses, each over 10 to 20 minutes, with about 50% of the total dose given initially and additional fractions (usually 25%) given at intervals of 6 to 8 hours if still indicated. Reconsider or reduce dose if treated with digoxin within previous 2 weeks. Commence oral maintenance therapy on the following day adjusted according to age, lean bodyweight and renal function.

**Maintenance dose:** variable but usually in the range 50–200 micrograms by IV infusion once daily. If the patient is already maintained on digoxin convert directly from previous oral maintenance dose (see below).

#### For existing patients switched from oral maintenance to parenteral dosing:

When switching from oral to IV the dose should be reduced by about 30% and to a measurable volume, e.g.

62.5 microgram tablet  $\cong$  50 micrograms by IV infusion.

125 microgram tablet  $\cong$  75 micrograms by IV infusion. 250 microgram tablet  $\cong$  150 micrograms by IV infusion.

Consider checking levels 7–10 days after a change in route, particularly in the treatment of AF.

**Dose in renal impairment:** consider reducing maintenance dose and monitoring levels if CrCl  ${<}50\,\text{mL/minute}.$ 

#### Intravenous infusion

#### Preparation and administration

- 1. Withdraw the required dose and add to a suitable volume of NaCl 0.9% or Gluc 5% (usually 100 mL but must be at least 4 times the injection volume). Mix well.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion via a volumetric infusion device usually over a minimum of 2 hours. For loading doses only, where a fraction is to be given, this may be infused over 10 to 20 minutes.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Digoxin-specific antibody fragments (Digibind, F(ab))

#### 38-mg dry powder vials

- · Digoxin-specific antibody fragments are derived from sheep immunised to digoxin.
- Treatment with Digibind is generally reserved for life-threatening digoxin or digitoxin toxicity where conventional treatments (i.e. drug withdrawal and correction of electrolyte abnormalities) are insufficient.
- Each 38-mg vial of Digibind renders 500 micrograms of digoxin or digitoxin pharmacologically inactive.

Standard digoxin serum assays cannot be used to determine free, pharmacologically active digoxin after administration of Digibind because these also detect F(ab)-bound digoxin.

#### **Pre-treatment checks**

- Previous exposure: Although allergic reactions have been reported rarely, patients known to be
  allergic to sheep protein and patients who have previously received digoxin-specific antibody
  fragments are likely to be at greater risk of developing an allergic reaction.
- If your laboratory calculates digoxin levels as nanomol/L, multiply that figure by 0.78 to convert to micrograms/L (nanograms/mL).
- Erroneous calculations may result from inaccurate estimates of the amount of digitalis ingested or absorbed or from non-steady-state serum digitalis concentrations. Inaccurate serum digitalis concentration measurements are a possible source of error; this is especially so for very high values, since most digoxin assay kits are not designed to measure values >5 nanograms/mL.

Biochemical and other tests (not all are necessary in an emergency situation)

| Digoxin plasma concentration | ECG        |
|------------------------------|------------|
| Electrolytes: serum K        | Bodyweight |

#### Dose

It is essential to consult a poisons information service, e.g. Toxbase at www.toxbase.org (password or registration required) for full details of the management of cardiac glycoside toxicity.

The dose is given in multiples of whole vials (rounding up) and is dependent on the amount of cardiac glycoside to be neutralised.

Acute ingestion of an <u>unknown</u> amount of cardiac glycoside where serum concentration is <u>not</u> available: 10 vials can be administered followed by an additional 10 vials if clinically indicated. This amount will be adequate to treat life-threatening ingestion in most adults. **Acute ingestion of <u>known</u> amount of cardiac glycoside:** use the following formula to calculate number of vials needed. See Table D4 for a rough guide to dose likely to be needed.

Dose (number of vials) = Total body load  $(mg)^* \times 2$ 

\*Total body load is *either* (dose in mg of digoxin  $\times$  0.8) *or* dose in mg digitoxin.

# Table D4 Estimated dose of Digibind to treat acute ingestion of a known quantity of digoxin

| Number of 250-microgram digoxin<br>tablets<br>(80% bioavailability assumed) | Digibind dose<br>(number of vials) |
|-----------------------------------------------------------------------------|------------------------------------|
| 25                                                                          | 10                                 |
| 50                                                                          | 20                                 |
| 75                                                                          | 30                                 |
| 100                                                                         | 40                                 |
| 150                                                                         | 60                                 |
| 200                                                                         | 80                                 |

# **Toxicity during chronic therapy where serum concentration is not available:** 6 vials will usually be adequate to reverse toxicity.

#### Toxicity during chronic therapy where serum concentration is available:

**For digoxin toxicity:** if serum concentration is known, use the following formulas to calculate number of vials needed. See Table D5 for a rough guide to dose likely to be needed. *Converting units:* nanomol/L  $\times$  0.78 = micrograms/L (or nanograms/mL).

 $Dose (number of vials) = \frac{Serum \ digoxin \ concentration \ (nanograms/mL) \times bodyweight \ (kg)}{100}$ 

#### For digitoxin toxicity:

 $\text{Dose (number of vials)} = \frac{\text{Serum digitoxin concentration (nanograms/mL)} \times \text{bodyweight (kg)}}{1000}$ 

# Intravenous infusion (preferred method)

- 1. Reconstitute each vial with 4 mL WFI and mix gently.
- Withdraw the contents from the required number of vials and add to a convenient volume of NaCl 0.9% (usually 100 mL).
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 30 minutes; through a 0.22-micron filter (if available) to remove any undissolved aggregates.

### **Bibliography**

SPC Digibind, GlaxoSmithKline UK (accessed 31 August 2009).

# Dihydrocodeine tartrate

#### 50 mg/mL solution in 1-mL ampoules

- Dihydrocodeine is an opioid analgesic.
- It is used for moderate to severe pain. It is less potent than morphine: dihydrocodeine 30 mg IM has the approximate analgesic effect of morphine sulfate 10 mg IM.

#### **Pre-treatment checks**

- Do not use in acute respiratory depression, where there is a risk of paralytic ileus, in raised intracranial pressure and in head injury, in comatose patients and phaeochromocytoma.
- Caution in JBP, shock, convulsive disorders, supraventricular tachycardias, atrial flutter, chronic
  obstructive pulmonary disease and acute asthma attack, obstructive or inflammatory bowel diseases, biliary tract diseases, alcoholism, prostatic hyperplasia, myasthenia gravis, hypothyroidism
  (reduce dose), adrenocortical insufficiency (reduce dose).
- · Caution in elderly patients use lower doses; initial dose should not exceed 25 mg.
- · Caution also in pancreatitis and severe cor pulmonale.
- Ensure resuscitation equipment and naloxone are available especially for IV administration.

#### Biochemical and other tests

Blood pressure and pulse LFTs Pain score Renal function: U, Cr, CrCl (or eGFR) Respiratory rate

#### Dose

Standard dose: up to 50 mg by IM or deep SC injection every 4–6 hours when required.
Elderly patients: reduce initial dose then adjust dose to response.
Dose in hepatic impairment: reduce dose or avoid.
Dose in renal impairment: reduce dose or avoid.

#### **Subcutaneous injection**

Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by deep SC injection.
- 3. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

#### Intramuscular injection

- 1. Withdraw the required dose.
- 2. Give by deep IM injection.
- 3. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

# Monitoring

Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving an initial dose, especially elderly patients or those of low bodyweight.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Dimercaprol (British Anti-Lewisite, BAL)

#### 100 mg/2 mL solution in ampoules

- · Dimercaprol is a chelator that combines with various metal ions.
- It is used in the treatment of acute poisoning by certain heavy metals: arsenic, mercury, gold, bismuth, antimony and possibly thallium. It has also been used with sodium calcium edetate in acute lead poisoning particularly acute lead encephalopathy.
- The sulfhydryl groups on dimercaprol compete with endogenous sulfhydryl groups on proteins such as enzymes to combine with these metals. The dimercaprol-metal complex formed is readily excreted by the kidney. The aim of treatment is to provide an excess of dimercaprol in body fluids until the excretion of the metal is complete.

Do not use in iron, cadmium or selenium poisoning as the dimercaprol-metal complexes formed are more toxic than the metals themselves.

#### **Pre-treatment checks**

- · Do not use in patients with peanut allergy as the injection contains arachis oil.
- · Do not use in patients with an allergy to soya.
- · Avoid use in impaired hepatic function unless due to arsenic poisoning.
- Use with care in patients with ↑BP or impaired renal function.

#### Biochemical and other tests

| Blood pressure | LFTs                                  |
|----------------|---------------------------------------|
| Bodyweight     | Renal function: U, Cr, CrCl (or eGFR) |

#### Dose

It is essential to consult a poisons information service, e.g. Toxbase at www.toxbase.org (password or registration required) for full details of the management of heavy metal toxicity.

**Standard dose:** 2.5–3 mg/kg bodyweight by IM injection every 4 hours for 2 days; then 2–4 times daily on the third day; then 1–2 times daily for 10 days or until recovery.

- Prophylactic or therapeutic administration of parenteral antihistamine or ephedrine 30 mg may prevent or relieve many of the mild adverse effects of dimercaprol.
- · Side-effects may also be reduced by giving injections at least 4 hours apart.

#### Intramuscular injection

Contains arachis oil – should not be given in peanut allergy. See Special handling below.

- 1. Withdraw the required dose.
- 2. Give by deep IM injection. Rotate injection sites for subsequent injections.

# Additional information

| Common and serious<br>undesirable effects | <ul> <li>Injection-related: Local: Local injection-site pain and gluteal abscess has occasionally been encountered (more common if not given by deep IM injection).</li> <li>Other: Side-effects are frequent, particularly at the higher dosage levels, but nearly always reversible:</li> <li>Elevation of BP accompanied by ↑pulse, nausea and possibly vomiting.</li> <li>Burning sensation of the lips, mouth, throat and eyes, salivation and lacrimation, conjunctivitis, rhinorrhoea.</li> <li>Muscle pain and spasm, abdominal pain.</li> <li>Headache, tingling of the hands and other extremities, a feeling of constriction in the chest and throat, sweating of the forehead and hands.</li> </ul> |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pharmacokinetics                          | After IM injection, maximum plasma concentrations of dimercaprol may be attained within 1 hour. It is rapidly metabolised and the metabolites and dimercaprol-metal chelates are excreted in the urine and bile. Elimination is essentially complete within 4 hours of a single dose.                                                                                                                                                                                                                                                                                                                                                                                                                           |

# Dipyridamole

#### 5 mg/mL solution in 2-mL ampoules

- · Dipyridamole is a coronary vasodilator and inhibits platelet aggregation.
- It is used IV as an alternative to exercise stress in thallium-201 myocardial imaging.
- · Risks associated with IV dosing need to be balanced against the risk of exercise stress.

#### **Pre-treatment checks**

- Do not use in dysrhythmias, second/third-degree atrioventricular block or sick sinus syndrome (unless controlled by pacemaker); systolic BP <90 mmHg, recent unexplained syncope (within 4 weeks), recent TIAs.
- Do not use in severe coronary artery disease, recent ACS, left ventricular outflow obstruction, haemodynamic instability; asthma; myasthenia gravis.
- · Oral dipyridamole therapy must be discontinued for 24 hours prior to IV dosing.

- · Caution in pre-existing first-degree heart block.
- Parenteral aminophylline should be readily available for relieving adverse effects such as bronchospasm or severe chest pain.

#### Biochemical and other tests

Bodyweight ECG Blood pressure Electrolytes: serum Na, K

#### Dose

**Standard dose:** 567 micrograms/kg by IV infusion over 4 minutes (at approximately 142 micrograms/kg/minute). Thallium-201 should be injected within 3–5 minutes following the 4-minute infusion.

#### Dose calculation:

Total dose in  $mL = \frac{567 \times bodyweight (kg)}{5000}$ 

### Intravenous infusion via a syringe pump

- 1. Withdraw the required total dose.
- Dilute to at least 3 times the original volume of dipyridamole injection with NaCl 0.9% or Gluc 5%, i.e. total volume 20–50 mL.
- 3. Cap the syringe and mix well.
- The solution should be clear and pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by IV infusion over 4 minutes using a syringe pump.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Persantin ampoules, Boehringer Ingelheim Limited (accessed 20 April 2010).

# Disodium folinate (sodium folinate)

#### 50 mg/mL solution in 2-mL, 8-mL and 18-mL vials

- · Disodium folinate is a derivative of tetrahydrofolic acid, the active form of folic acid.
- It is used as an antidote to folic acid antagonists such as methotrexate (commonly known as 'folinic acid rescue' or 'folinate rescue') and as an adjunct to fluorouracil (FU) in the treatment of colorectal cancer.
- Doses are usually expressed in terms of folinic acid: Folinic acid 1 mg ≅ 1.09 mg of disodium folinate.

#### **Pre-treatment checks**

• Do not give if the patient is anaemic owing to vitamin B<sub>12</sub> deficiency.

#### Biochemical tests

Electrolytes: serum Na, K, Ca FBC LFTs Renal function: U, Cr, CrCl (or eGFR)

#### Dose

Disodium folinate must not be administered intrathecally.

Consult specialist literature as regimens vary greatly depending on the indication.

#### Intravenous injection

- 1. Withdraw the required dose.
- 2. The solution should be clear and slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 1 minute.

# Intermittent intravenous infusion

### Preparation and administration

- 1. Withdraw the required dose and add to a convenient volume of NaCl 0.9%.
- The solution should be clear and colourless to slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 1–2 hours.

| This assessment is based on the full range of preparation and administration options described in the<br>monograph. These may not all be applicable in some clinical situations. |                                                                                                                                                                                                                                                       |

# **Bibliography**

SPC Sodiofolin 50 mg/mL, solution for injection (accessed 5 April 2009).

# Disodium levofolinate (sodium levofolinate)

#### 50 mg/mL solution in 1-mL, 4-mL and 9-mL vials

- · Disodium levofolinate is a derivative of tetrahydrofolic acid, the active form of folic acid.
- It is used as an antidote to folic acid antagonists such as methotrexate (commonly known as 'levofolinic acid rescue' or 'levofolinate rescue') and as an adjunct to fluorouracil (FU) in the treatment of colorectal cancer.
- Doses are usually expressed in terms of folinic acid: Folinic acid 1 mg  $\approx$  1.09 mg of disodium levofolinate.

#### **Pre-treatment checks**

Do not give if the patient is anaemic owing to vitamin B<sub>12</sub> deficiency.

#### Biochemical and other tests

Electrolytes: serum Na, K, Ca FBC LFTs Renal function: U, Cr

#### Dose

Disodium levofolinate must not be administered intrathecally.

Consult specialist literature as regimens vary greatly depending on the indication.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. The solution should be clear and slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 1 minute.

#### Intermittent intravenous infusion

#### Preparation and administration

- 1. Withdraw the required dose and add to a convenient volume of NaCl 0.9% or Gluc 5%.
- 2. The solution should be clear and colourless to slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 2 hours.

# Disopyramide

#### 10 mg/mL solution in 5-mL ampoules

- Disopyramide phosphate is a class Ia antiarrhythmic drug, with effects similar to those of procainamide. It also has antimuscarinic and negative inotropic properties.
- · It is used only in management of life-threatening arrhythmias.
- Doses are expressed in terms of the base: Disopyramide 10 mg ≈ 12.88 mg disopyramide phosphate.

#### **Pre-treatment checks**

- Avoid in severe heart failure, second- and third-degree heart block and sinus node dysfunction (unless a pacemaker is fitted) and cardiogenic shock.
- Caution in ventricular fibrillation or torsade de pointes, atrial flutter or atrial tachycardia with partial block, bundle branch block, heart failure.
- · Caution in prostatic enlargement and susceptibility to angle-closure glaucoma.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Bodyweight            | LFTs                                  |
|-----------------------|---------------------------------------|
| ECG                   | Renal function: U, Cr, CrCl (or eGFR) |
| Electrolytes: serum K |                                       |

#### Dose

The maximum dose by all routes is 800 mg in 24 hours.

**Standard dose:** give 2 mg/kg (maximum 150 mg) by IV injection. Arrhythmia usually resolves within 15 minutes. If successful continue with oral therapy. The IV dose can be repeated cautiously if the arrhythmia recurs (maximum dose 300 mg or 4 mg/kg within the first hour).

**Serious arrhythmias or inability to take oral medication:** give 2 mg/kg (maximum 150 mg) by IV injection followed by 20–30 mg/hour (or 400 micrograms/kg/hour) by IV infusion up to a maximum of 800 mg in 24 hours.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 5 minutes (maximum 30 mg/minute).

#### Intravenous infusion

- 1. Withdraw the required dose.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Add to a convenient volume of NaCl 0.9% or Gluc 5%.
- 4. Give by IV infusion via a volumetric pump.

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |  |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Rythmodan injection, Sanofi-Aventis (accessed 14 June 2010).

# **Dobutamine**

#### 12.5 mg/mL solution in 20-mL ampoules

- Dobutamine hydrochloride is a cardiac stimulant producing a positive inotropic effect on the myocardium that results in \cardiac output (\mathcal{myocardial contractility, \mathcal{stroke volume}). Its use requires intensive haemodynamic monitoring and ideally should be confined to the critical care setting.
- It is used to provide positive inotropic support in treatment of cardiac decompensation due to depressed contractility; in cardiogenic shock (heart failure with severe LBP) and in septic shock in combination with dopamine.

- It may also be used in cardiac stress testing if the patient cannot undergo a period of exercise or if the exercise yields no useful information (dobutamine stress echocardiography).
- Doses are expressed in terms of the base: Dobutamine 1 microgram ≅ 1.12 micrograms dobutamine hydrochloride.

#### **Pre-treatment checks**

- Do not use in mechanical obstruction of ventricular filling and/or outflow, hypovolaemia.
- · Consult product literature for full details of exclusions to use in stress echocardiography.
- · Consider the risk of sulfite sensitivity in patients with asthma.
- Inadequate circulating blood volume should be restored prior to treatment with dobutamine.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Bodyweight Electrolytes: serum K

#### Dose

**Inotropic effect**: initiate at 2.5 micrograms/kg/minute by IV infusion into a central or large peripheral vein. This can be gradually increased to 10 micrograms/kg/minute as necessary according to heart rate, BP, cardiac output and urine output.

- Doses of 0.5-40 micrograms/kg/minute may be required.
- Discontinue treatment gradually.

**Cardiac stress testing**: initially 5 micrograms/kg/minute for 3–8 minutes increasing by 5 micrograms/kg/minute every 3–8 minutes, up to a usual maximum of 20 micrograms/kg/minute (occasionally up to 40 micrograms/kg/minute may be required).

#### Continuous intravenous infusion via a syringe pump

The concentration used is dependent on the patient's dosage and fluid requirements but the final concentration must be no greater than 5 mg/mL. A concentration of 1 mg/mL has been recommended for cardiac stress testing.

Administer into a central or large peripheral vein.

#### Preparation of a 5 mg/mL solution

- 1. Withdraw 250 mg (20 mL) of the concentrate and make up to 50 mL in a syringe pump with Gluc 5% or NaCl 0.9%.
- 2. Cap the syringe and mix well to give a solution containing 5 mg/mL (5000 micrograms/mL).
- The solution should be clear and no more than faintly pink in colour. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

- 1. Give by IV infusion via a syringe pump at an initial rate of 2.5 micrograms/kg/minute.
- 2. Adjust dose according to clinical response.
- 3. Prepare a fresh syringe every 24 hours.

#### **Calculation of infusion rate:**

 $Infusion \ rate \ (mL/hour) = \frac{Weight \ (kg) \times required \ rate \ (micrograms/minute) \times 60}{Concentration \ of \ prepared \ infusion \ (micrograms/mL)}$ 

See Table D6 below for a dosage chart detailing pre-calculated infusion rates for each bodyweight using a 5 mg/mL (5000 micrograms/mL) solution.
#### 270 | Dobutamine

# Table D6 Dobutamine rate of infusion using dobutamine 250 mg made up to 50mL in a 50-mL syringe pump (5000 micrograms/mL)

# **Dopamine hydrochloride**

#### 40 mg/mL and 160 mg/mL solution in 5-mL ampoules 40 mg/mL solution in 5-mL and 10-mL vials

#### $400\,mg$ (1.6 mg/mL) and $800\,mg$ (3.2 mg/mL) solution in 250-mL infusion bags

- Dopamine hydrochloride is a cardiac stimulant producing a positive inotropic effect on the myocardium that results in *\cardiac* output (*\myocardial* contractility, *\stroke* volume). Its use requires intensive haemodynamic monitoring and ideally should be confined to the critical care setting.
- It is used to treat acute \u03c4BP or shock and \u03c4cardiac output associated with MI, septicaemia, trauma
  and renal failure; persistent \u03c4BP after open heart surgery; maintaining urine output. In many
  centres its use has been superseded by dopexamine.

#### **Pre-treatment checks**

- Do not use in phaeochromocytoma, hyperthyroidism, uncorrected atrial or ventricular tachyarrhythmias, ventricular fibrillation.
- An inadequate circulating blood volume should be restored prior to treatment with dopamine.

#### Biochemical and other tests

Bodyweight Electrolytes: serum Na, K Renal function: U, Cr, CrCl (or eGFR)

#### Dose

**Inotropic effect:** initiate at 2–5 micrograms/kg/minute by IV infusion into a central or large peripheral vein. This can be gradually increased by up to 5–10 micrograms/kg/minute according to BP, cardiac output and urine output. Up to 20–50 micrograms/kg/minute may be required in seriously ill patients.

- Dose cautiously in patients with shock following MI.
- Discontinue treatment gradually.

#### **Continuous intravenous infusion**

The concentration used is dependent on the patient's dosage and fluid requirements. Concentrations greater than 3.2 mg/mL must be given via a central line.

#### Preparation of a 1.6 mg/mL (1600 micrograms/mL) solution

Ideally use a pre-prepared infusion bag containing 400 mg/250 mL. Alternatively:

- 1. Withdraw 400 mg of the dopamine concentrate into a syringe (see Table D7).
- 2. Withdraw an equal volume of fluid from a 250-mL bag of NaCl 0.9% or Gluc 5% and discard.
- 3. Add the dopamine concentrate to the prepared infusion bag and mix well. This gives a solution containing 1.6 mg/mL (1600 micrograms/mL).

#### Preparation of a 3.2 mg/mL (3200 micrograms/mL) solution

Ideally use a pre-prepared infusion bag containing 800 mg/250 mL. Alternatively:

- 1. Withdraw 800 mg of the dopamine concentrate into a syringe (see Table D7).
- 2. Withdraw an equal volume of fluid from a 250-mL bag of NaCl 0.9% or Gluc 5% and discard.
- 3. Add the dopamine concentrate to the prepared infusion bag and mix well. This gives a solution containing 3.2 mg/mL (3200 micrograms/mL).

| 40                                    | 5                                                              | 10  | 20                                           |  |  |  |  |
| 160                                   | 1.25                                                           | 2.5 | 5                                            |  |  |  |  |

#### Administration

- The solution should be clear and almost colourless (the concentrate may have a pale straw colour). Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV infusion via a volumetric infusion device into a large vein at an initial rate of 2– 5 micrograms/kg/minute.
- 3. Adjust the dose according to clinical response.
- 4. Prepare a fresh infusion bag every 24 hours.

## Continuous intravenous infusion via a syringe pump

For administration via a central line only.

#### Preparation of a 4 mg/mL (4000 micrograms/mL) solution

- 1. Withdraw 200 mg of the concentrate and make up to  $50 \,\text{mL}$  in a syringe pump with NaCl 0.9%, Gluc 5% or Hartmann's.
- 2. Cap the syringe and mix well to give a solution containing 4 mg/mL (4000 micrograms/mL).
- The solution should be clear and almost colourless (the concentrate may have a pale strawcolour). Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

- Give by IV infusion via a syringe pump into a central line at an initial rate of 2–5 micrograms/kg/ minute.
- 2. Adjust the dose according to clinical response.
- 3. Prepare a fresh syringe every 24 hours.

#### **Calculation of infusion rate:**

 $Infusion \ rate \ (mL/hour) = \frac{Weight \ (kg) \times required \ rate \ (micrograms/minute) \times 60}{Concentration \ of \ prepared \ infusion \ (micrograms/mL)}$ 

See Tables D8, D9 and D10 below for dosage charts detailing pre-calculated infusion rates for each bodyweight using 1.6 mg/mL (1600 micrograms/mL), 3.2 mg/mL (3200 micrograms/mL) and 4 mg/mL (4000 micrograms/mL) solutions.

# **Dopexamine hydrochloride**

#### 10 mg/ml solution in 5-mL ampoules

- Dopexamine is a mildly inotropic sympathomimetic agent. It stimulates beta<sub>2</sub>-adrenoceptors and peripheral dopamine receptors; it inhibits neuronal uptake of noradrenaline.
- It is used for afterload reduction in treatment of exacerbations of chronic heart failure, or to
  provide short-term haemodynamic support in heart failure associated with cardiac surgery.
- It has also been used (unlicensed) in critically ill patients to *splanchnic blood flow* with the aim of
  preventing renal and GI dysfunction.

#### **Pre-treatment checks**

- An inadequate circulating blood volume should be restored prior to and during treatment with dopexamine.
- Do not use in phaeochromocytoma, thrombocytopenia, left ventricular outlet obstruction such as hypertrophic obstructive cardiomyopathy or aortic stenosis.
- Caution in MI or recent angina, ↓K, hyperglycaemia, ↓BP; restrict sodium and fluid load during administration.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Blood glucose |  |
|---------------|--|
| Bodyweight    |  |

Electrolytes: serum K Platelets

#### Dose

**Standard dose:** initiate at 500 nanograms/kg/minute by IV infusion into a central or large peripheral vein. This can be increased to 1microgram/kg/minute and further increased up to 6 micrograms/kg/minute in increments of 0.5–1 microgram/kg/minute at intervals of not less than 15 minutes.

- Discontinue treatment gradually.
- Therapy beyond 48 hours has not been fully evaluated.

#### **Continuous intravenous infusion**

The concentration used is dependent on the patient's dosage and fluid requirements. The final concentration must be no greater than 1 mg/mL via a large peripheral vein, or 4 mg/mL via a central line.

#### Preparation of a 0.8 mg/mL (800 micrograms/mL) solution

- 1. Withdraw 20 mL from a 250-mL bag of NaCl 0.9%, Gluc 5% or Hartmann's and discard.
- 2. Withdraw 200 mg (20 mL) of the dopexamine concentrate into a syringe.
- 3. Add the dopexamine concentrate to the prepared infusion bag and mix well. This gives a solution containing 800 micrograms/mL.
- The solution should be clear and colourless to very pale pink. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

- 1. Give by IV infusion via a volumetric infusion device into a large vein at an initial rate of 500 nanograms/kg/minute.
- 2. Adjust dose according to clinical response.
- 3. Prepare a fresh infusion bag every 24 hours.

## Continuous intravenous infusion via a syringe pump

For administration via a central line only.

#### Preparation of a 4 mg/mL (4000 micrograms/mL) solution

- 1. Withdraw 200 mg (20 mL) of the dopexamine concentrate and make up to 50 mL in a syringe pump with NaCl 0.9%, Gluc 5% or Hartmann's.
- 2. Cap the syringe and mix well to give a solution containing 4 mg/mL (4000 micrograms/mL).
- 3. The solution should be clear and colourless to very pale pink. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

- Give by IV infusion via a syringe pump into a central line at an initial rate of 500 nanograms/kg/ minute.
- 2. Adjust dose according to clinical response.
- 3. Prepare a fresh syringe every 24 hours.

#### **Calculation of infusion rate:**

 $Infusion \ rate \ (mL/hour) = \frac{Weight \ (kg) \times required \ rate \ (micrograms/minute) \times 60}{Concentration \ of \ prepared \ infusion \ (micrograms/mL)}$ 

See Tables D11 and D12 below for dosage charts detailing pre-calculated infusion rates for each bodyweight using 800 micrograms/mL and 4 mg/mL (4000 micrograms/mL) solutions.

Table D12 Dopexamine rate of infusion (central line administration only) using dopexamine 200 mg made up to 50 mL in a 50-mL syringe

# Doripenem

#### 500-mg dry powder vials

- Doripenem is a synthetic carbapenem beta-lactam antibiotic related to other carbapenems (e.g. ertapenem, imipenem, meropenem). It is more stable to renal dehydropeptidase I than imipenem, meaning that it does not need to be combined with cilastatin to be effective.
- It is used to treat nosocomial pneumonia (including ventilator-associated pneumonia), complicated intra-abdominal infections and complicated urinary tract infections.

#### **Pre-treatment checks**

 Do not give if there is known hypersensitivity to any carbapenem antibacterial agent or previous immediate hypersensitivity reaction to penicillins or cephalosporins.

#### Biochemical and other tests

Renal function: U, Cr, CrCl (or eGFR)

#### Dose

Doripenem must not be given by inhalation as this has resulted in pneumonitis.

#### Standard dose: 500 mg every 8 hours.

Dose in renal impairment: adjusted according to creatinine clearance:

- CrCl >50 mL/minute: dose as in normal renal function.
- CrCl 30-50 mL/minute: 250 mg every 8 hours.
- CrCl <30 mL/minute: 250 mg every 12 hours.

#### Intermittent intravenous infusion

#### Preparation and administration

- 1. Add 10 mL WFI or NaCl 0.9% to each 500-mg vial and shake to form a suspension.
- 2. Withdraw the contents of the vial and add to 100 mL NaCl 0.9%.
- 3. Mix until completely dissolved.
- The solution should be clear and colourless to slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by IV infusion over 1 hour (in the case of severe infections including nosocomial pneumonia this may be increased to 4 hours, which allows the serum concentration to be maintained above the MIC for a longer period of time).

#### Preparation of a 250-mg dose

The manufacturer recommends following steps 1–4 above and removing and discarding 55 mL of the prepared solution from the infusion bag. Give the remainder by IV infusion over 1 hour.

| Technical information          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |  |  |  |  |  |

| This assessment is based on the full range of propagation and administration entions described in the |                                                                                  |  |  |  |  |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

#### Reference

1. Communication with manufacturer, 24 April 2009.

#### **Bibliography**

SPC Doribax 500 mg powder for solution for infusion (accessed 13 April 2009).

# Doxapram hydrochloride

#### 2 mg/mL solution in 500-mL infusion bag 20 mg/mL solution in 5-mL ampoules

- Doxapram hydrochloride is a central and respiratory stimulant with a brief duration of action. It
  acts by stimulating peripheral chemoreceptors and central respiratory centres. Despite ↑respiratory
  rate and volume, arterial O<sub>2</sub> is rarely improved because doxapram ↑work of breathing (i.e. ↑O<sub>2</sub>
  consumption = ↑CO<sub>2</sub> production).
- Doxapram antagonises the respiratory depressant effects of opioids without interfering with their analgesic properties.
- It has been used in the treatment of ventilatory failure in patients with COPD, but has been largely
  superseded by ventilatory support. However, if ventilatory support is contraindicated in patients
  with hypercapnic respiratory failure who are becoming drowsy or comatose, doxapram may revive
  patients so that they can cooperate and clear secretions.

#### 288 | Doxapram hydrochloride

#### **Pre-treatment checks**

- Respiratory stimulants can be harmful in respiratory failure as they also stimulate non-respiratory muscles. They must only be given under expert supervision in hospital combined with physiotherapy.
- Do not use in severe hypertension, status asthmaticus, coronary artery disease, thyrotoxicosis, epilepsy, recent head injury or physical obstruction of the respiratory tract.
- Give with caution in hypertension (avoid if severe), impaired cardiac reserve, hepatic impairment (doxapram is primarily metabolised by the liver).
- Use in pregnancy only if compelling reasons.
- · Protect the airway because of the risk of vomiting and aspiration.
- Give with oxygen in severe irreversible airways obstruction or severely decreased lung compliance (because of \u00e7workload of breathing).
- Give with a beta2-agonist in bronchoconstriction.
- Delay doxapram use for at least 10 minutes following discontinuation of anaesthetics known to sensitise the myocardium to catecholamines, e.g. halothane, because of possible *îadrenaline* release.

#### Biochemical and other tests

| ABGs and pH              | Bodyweight |
|--------------------------|------------|
| Blood pressure and pulse | LFTs       |

#### Dose

Doxapram has a narrow margin of safety so the minimum effective dosage should be used.

#### Postoperative respiratory depression:

- 1-1.5 mg/kg bodyweight by IV injection. Repeat at 1-hour intervals if necessary.
- May also be given by IV infusion at an initial rate of 2–3 mg/minute adjusted according to patient response.

**Respiratory failure**: 1.5–4 mg/minute by IV infusion depending on condition and response of the patient. Table D13 shows a dosage regimen that has been shown to result in the rapid achievement of a steady-state plasma concentration of doxapram.

| Time from start of infusion (minutes) | Rate        | Using 2 mg/mL infusion solution: |                |  |  |  |  |

# Table D13 A doxapram dosing regiment

# Intravenous injection

#### Preparation and administration

- 1. Using the 20 mg/mL preparation, withdraw the required dose.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 30 seconds.

#### **Continuous intravenous infusion**

#### Preparation and administration

- 1. Use the pre-prepared IV infusion containing doxapram 2 mg/mL in Gluc 5%.
- 2. Give by IV infusion up to a maximum rate of 4 mg/minute (i.e. 2 mL/minute, 120 mL/hour).

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Dopram infusion: doxapram hydrochloride 2 mg/ml solution for infusion (received by e-mail 16 February 2009).

SPC Dopram injection (received by e-mail 16 February 2009).

# Enfuvirtide

#### 90 mg/mL dry powder vials with solvent (WFI)

- · Enfuvirtide is an HIV fusion inhibitor that interferes with entry of HIV into cells.
- · It is used with other antiretrovirals in the management of HIV infection.

#### **Pre-treatment checks**

• Use with caution in hepatic impairment.

#### Dose

Standard dose: 90 mg twice daily.

#### **Subcutaneous injection**

#### Preparation and administration

Vials contain 108 mg of enfuvirtide providing 90 mg/mL after reconstitution.

- 1. Withdraw 1.1 mL of the diluent (WFI) and add to the powder vial.
- Gently tap the vial with a fingertip until the powder begins to dissolve. The vial **must not** be shaken or turned upside down as this will cause excessive foaming.
- After the powder begins to dissolve it may be set aside to allow complete dissolution; this may take up to 45 minutes. Gently rolling the vial between the hands may reduce this time.
- 4. The resulting solution contains 90 mg/mL enfuvirtide. It should be clear and bubble-free. Inspect visually for visible particles or cloudiness and discard if present.
- Withdraw the required dose from the vial and give by SC injection into the upper arm, anterior thigh or abdomen (avoiding the navel).
- Each injection should be given at a site different from the preceding injection.
- Injections should not be made into areas where the skin shows signs of a previous injection site
  reaction or near anatomical areas where large nerve tracts lie close to the skin, e.g. near the elbow,
  knee, groin, inferior or medial section of the buttocks.
- Also avoid injecting directly over blood vessels, into skin abnormalities, moles, scars (including surgical scars), bruises, tattoos or burn sites.

| Pharmacokinetics                          | Elimination half-life is 3.8 hours.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Significant<br>interactions               | None reported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Action in case of overdose                | No specific antidote. Stop administration and give supportive therapy as appropriate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Counselling                               | Patients should be advised to seek medical advice if they experience joint aches<br>and pain, joint stiffness or difficulty in movement (possible signs of<br>osteonecrosis). Also to seek immediate medical advice if there are signs of<br>hypersensitivity.                                                                                                                                                                                                                                                                                                         |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

## **Bibliography**

SPC Fuzeon (accessed 16 March 2009).

# **Enoxaparin sodium**

# 100 mg/mL solution in 20-mg, 40-mg, 60-mg, 80-mg, 100-mg pre-filled syringes and 3-mL vials 150 mg/mL solution in 120-mg, 150-mg pre-filled syringes

- · Enoxaparin sodium is low-molecular-weight heparin.
- It is used in the treatment of STEMI and also in the acute coronary syndromes: unstable angina and NSTEMI.
- It is used in the treatment of VTE, i.e. pulmonary embolism and deep vein thrombosis.
- It is used for prophylaxis of VTE in surgical and medical patients and to prevent thrombus formation in extracorporeal circulation during haemodialysis.
- Not all products are licensed for all indications.
- Enoxaparin sodium 1 mg ≈ 100 units of anti-Factor Xa activity.

#### **Pre-treatment checks**

- Avoid in acute bacterial endocarditis, major bleeding or high risk of uncontrolled haemorrhage including recent haemorrhagic stroke.
- In treatment dosage it is contraindicated in patients undergoing locoregional anaesthesia in elective surgical procedures.
- Placement or removal of a spinal/epidural catheter should be delayed for 10–12 hours after administration of prophylactic doses, whereas patients receiving higher doses (1.5 mg/kg once daily) require a 24 hours delay. Subsequent enoxaparin doses should be given no sooner than 4 hours after catheter removal.
- Caution with other drugs affecting haemostasis, such as aspirin or clopidogrel.
- Use with extreme caution in patients with a history of HIT.
- Patients with severe renal or hepatic impairment may need a reduced dose (or at least closer monitoring of ADRs).

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Bodyweight (for certain indications) | LFTs                                  |
|--------------------------------------|---------------------------------------|
| Electrolytes: serum K                | Platelet count                        |
| INR                                  | Renal function: U, Cr, CrCl (or eGFR) |

#### Dose

#### Prophylaxis

**Low to moderate risk of VTE:** 20 mg by SC injection once daily until the patient is mobile. In patients undergoing surgery, the initial dose is given approximately 2 hours preoperatively.

**Orthopaedic surgery and high risk of VTE:** 40 mg by SC injection once daily until the patient is mobile. The initial dose is given approximately 12 hours preoperatively.

**Medical patients (high risk of VTE):** 40 mg by SC injection once daily until the patient is mobile for a maximum of 14 days.

**Prevention of extracorporeal thrombus formation during haemodialysis**: 1 mg/kg introduced into the arterial line at the start of dialysis session. A second dose of 0.5–1 mg/kg may be given after 4 hours if fibrin rings are found. For patients at a high risk of haemorrhage the dose should be reduced to 0.5 mg/kg for double vascular access or 0.75 mg/kg for single vascular access.

#### Treatment

**Treatment of VTE:** 1.5 mg/kg by SC injection once daily for at least 5 days and until INR is >2. **Treatment of ACS:** 1 mg/kg by SC injection every 12 hours, for a minimum of 2 days until clinically stable.

**Treatment of acute STEMI:** 30 mg by IV injection plus 1 mg/kg by SC injection. This is followed by 1 mg/kg by SC injection every 12 hours (maximum 100 mg for the first two SC doses only) for 8 days or until hospital discharge, whichever comes first. **For patients**  $\geq$ **75 years of age**, omit the IV dose and give 0.75 mg/kg by SC injection every 12 hours (maximum 75 mg for the first two SC doses only).

**Use in acute STEMI with a fibrinolytic:** as above but give enoxaparin between 15 minutes before and 30 minutes after the start of fibrinolytic therapy.

**Use in acute STEMI with PCI:** if the last SC dose of enoxaparin was given <8 hours before balloon inflation, no additional dosing is needed. If the last SC dose was given >8 hours before balloon inflation, give 0.3 mg/kg enoxaparin by IV injection.

Dose in renal impairment: dose is adjusted depending on indication and CrCl. See Table E1.

| 1 V                                                                               | 1                                                                                |

#### Table E1 Enoxaparin dosing in renal impairment

Patients  $\geq$ 75 years of age (for acute STEMI indication only)

0.75 mg/kg SC twice daily without initial IV dose

1 mg/kg SC once daily without initial IV dose

#### **Subcutaneous injection**

#### Preparation and administration

- 1. Select the correct pre-filled syringe. Pre-filled syringes are ready for immediate use: do not expel the air bubble.
  - If using multidose vials, withdraw the required dose using a needle suitable for SC administration.
- 2. The patient should be seated or lying down.
- 3. Pinch up a skin fold on the abdominal wall between the thumb and forefinger and hold throughout the injection.
- 4. Give by deep SC injection into the thick part of the skin fold at right angles to the skin. Do not rub the injection site after administration. Alternate doses between the right and left sides.

#### Intravenous injection (acute STEMI only)

#### Preparation and administration

- 1. Withdraw the required dose from a multidose vial, or select an appropriately sized pre-filled syringe and expel the air bubble and excess enoxaparin.
- 2. The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Flush the line with NaCl 0.9% or Gluc 5%.
- 4. Give by IV injection over 5 seconds and then flush with NaCl 0.9% or Gluc 5%.

## Arterial line injection (haemodialysis circuits)

#### Preparation and administration

- 1. Withdraw the required dose from a multidose vial, or select an appropriately sized pre-filled syringe and expel the air bubble and excess enoxaparin.
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give over 5 seconds via a port into the arterial limb of the haemodialysis circuit.

# **Bibliography**

SPC Clexane pre-filled syringes and multi-dose vial (accessed 2 June 2009).

monograph. These may not all be applicable in some clinical situations.

# Enoximone

#### 5 mg/mL solution in 20-mL ampoules

- · Enoximone is a phosphodiesterase type 3 inhibitor with positive inotropic and vasodilator activity.
- It is now used parenterally only for short-term management of heart failure unresponsive to other treatments.

#### **Pre-treatment checks**

- Use with caution in heart failure associated with hypertrophic cardiomyopathy, stenotic or obstructive valvular disease or other outlet obstruction.
- The injection solution is strongly alkaline and must be diluted with an equal volume of NaCl 0.9% or WFI before use.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Bodyweight | Platelet count                        |
|------------|---------------------------------------|
| LFTs       | Renal function: U, Cr, CrCl (or eGFR) |

#### Dose

- **Standard dose by IV injection:** initially 0.5–1 mg/kg by slow IV injection, then 500 micrograms/kg every 30 minutes until satisfactory response or total of 3 mg/kg given. For maintenance, the initial dose of up to 3 mg/kg may be repeated every 3–6 hours as required.
- **Standard dose by IV infusion:** initially 90 micrograms/kg/minute by IV infusion over 10–30 minutes, followed by intermittent or continuous infusion of 5–20 micrograms/kg/minute. Total dose over 24 hours should not usually exceed 24 mg/kg.
- Dose in renal and hepatic impairment: doses should be reduced and ideally levels should be monitored during continuous infusions.

#### Intravenous injection

Enoximone is incompatible with Gluc 5%. See Special handling and Spillage below.

#### 298 | Enoximone

#### Preparation and administration

- 1. Withdraw the required dose and dilute with an equal volume of NaCl 0.9% or WFI to give a solution containing 2.5 mg/mL.
- The solution should be clear and yellow in colour. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by slow IV injection at a maximum rate of 12.5 mg/minute (5 mL/minute of the diluted injection solution).

#### Continuous intravenous infusion via a syringe pump

Enoximone is incompatible with Gluc 5%. See *Special handling* and *Spillage* below.

#### To prepare a 2.5 mg/mL (2500 micrograms/mL) solution

- 1. Withdraw 100 mg (20 mL) of injection and make up to 40 mL in a syringe with NaCl 0.9%.
- 2. Cap the syringe and mix well to produce a solution containing 2.5 mg/mL (2500 micrograms/mL).
- The solution should be clear and yellow in colour. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

- 1. Give by IV infusion via a syringe pump as described under Dose above.
- 2. Adjust the dose according to clinical response.
- 3. Prepare a fresh syringe every 24 hours.

#### **Calculation of infusion rate:**

 $Infusion \ rate \ (mL/hour) = \frac{Weight \ in \ kg \times required \ rate \ (micrograms/minute) \times 60}{Concentration \ of \ prepared \ infusion \ (micrograms/mL)}$ 

See Table E2 below for a dosage chart detailing pre-calculated infusion rates for each bodyweight using a 2.5 mg/mL (2500 micrograms/mL) solution.

# **Ephedrine hydrochloride**

#### 3 mg/mL solution in 10-mL ampoules; 30 mg/mL solution in 1-mL ampoules

- Ephedrine hydrochloride is a sympathomimetic with direct and indirect effects on adrenergic receptors. It is less potent than adrenaline (epinephrine) but has a more prolonged action. It *†BP* by both peripheral vasoconstriction and by *†*cardiac output. It is less likely than adrenaline to *†*pulse.
- It is given parenterally to combat ↓BP during spinal or epidural anaesthesia; the risk of ↓BP with spinal or epidural block is greater than with other forms of nerve block. It is ineffective in ↓BP due to shock, circulatory collapse or haemorrhage.

#### **Pre-treatment checks**

- Caution in hyperthyroidism, diabetes mellitus, ischaemic heart disease, hypertension, susceptibility to angle-closure glaucoma, elderly patients, pregnancy.
- May cause acute urine retention in prostatic hypertrophy.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure TFTs

#### Dose

**Reversal of hypotension from spinal or epidural anaesthesia**: 3–6 mg (max. 9 mg) given by slow IV injection of a solution containing 3 mg/mL. This is repeated every 3–4 minutes according to response up to a maximum of 30 mg.

#### Intravenous injection

#### Preparation and administration

Note: the total maximum dose of 30 mg is given gradually in increments of 3-6 mg.

- 1. Withdraw the required dose. If using the 30 mg/mL product, dilute to 3 mg/mL with NaCl 0.9%.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 3-4 minutes in increments of 3-6 mg (1-2 mL of the dilute 3 mg/mL injection).

| Pharmacokinetics                          | Elimination half-life is 3-6 hours. If urine $\ensuremath{pH}$ is low elimination is closer to 3 hours.                                                                                                                                                                                                                                                                                                                         |
| Significant<br>interactions               | <ul> <li>Ephedrine may flevels or effect of the following drugs (or fside-effects): rasagiline (avoid combination), MAOIs (risk of hypertensive crisis, avoid combination and use within 2 weeks of withdrawal), moclobemide (risk of hypertensive crisis, avoid combination, and use within 2 weeks of withdrawal).</li> <li>Ephedrine may ilevels or effect of adrenergic neurone blockers (i hypotensive effect).</li> </ul> |
| Action in case of overdose                | No specific antidote. Stop administration and give supportive therapy as appropriate.                                                                                                                                                                                                                                                                                                                                           |

Risk rating: AMBER

 $\label{eq:score} \begin{array}{l} \mbox{Score} = 3 \\ \mbox{Moderate-risk product: Risk-reduction strategies are recommended.} \end{array}$ 

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Ephedrine hydrochloride injection 3 mg/mL Aurum, September 2005 version.

# Epoprostenol (PGI<sub>2</sub>, PGX, prostacyclin)

#### 0.5-mg and 1.5-mg dry powder vials with 50 mL glycine buffer solvent and filter

Epoprostenol must not be confused with its analogue iloprost (both names are sometimes erroneously used interchangeably).

- · Epoprostenol is a prostaglandin that causes vasodilatation and has platelet de-aggregant properties.
- It is used to prevent platelet aggregation in extracorporeal circuits, e.g. in renal dialysis particularly where use of heparin is contraindicated because of *î*risk of bleeding or for other reasons.
- It is also indicated for the treatment of primary pulmonary hypertension (PPH) in NYHA Class III and Class IV patients who do not respond adequately to conventional therapy. It was originally introduced into the management of end-stage PPH to sustain patients long enough for them to have heart-lung transplantation; however, long-term therapy may also have a role as an alternative to transplantation.
- Epoprostenol has many unlicensed uses including peripheral vascular disease, e.g. severe Raynaud syndrome.
- Many centres have their own protocols for dosing and handling epoprostenol and these should be followed where available.
- Doses are expressed in terms of the base: Epoprostenol 1 nanogram ≈ 1.06 nanograms epoprostenol sodium.

#### **Pre-treatment checks**

- · Avoid in severe left ventricular dysfunction.
- Caution in concomitant anticoagulant therapy or drugs that ↑risk of bleeding (monitoring is required when given with heparin).
- Other cautions include: haemorrhagic diathesis; dose titration for PPH should be in hospital (risk of pulmonary oedema); and pregnancy.
- Caution also in elderly patients (dose choice should reflect the greater frequency of \Lepatic, renal
  or cardiac function and of concomitant disease or other drug therapy in this cohort).

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Blood glucose level in diabetic patients | FBC including platelets |
|------------------------------------------|-------------------------|
| Blood pressure                           | Heart rate              |
| Bodyweight                               | Renal function: U, Cr   |

#### Dose

**Renal dialysis**: 4 nanograms/kg/minute by IV infusion prior to dialysis, then during dialysis give 4 nanograms/kg/minute as a continuous infusion into the arterial inlet of the dialyser. Stop the infusion at the end of dialysis.

Primary pulmonary hypertension: see product literature for details. Severe Raynaud's syndrome (unlicensed): doses vary – consult your local protocol. Calculation of infusion rate (see also Table E3 below):

 $Infusion \ rate \ (mL/hour) = \frac{Dose \ (nanograms/kg/minute) \times bodyweight \times 60}{Concentration \ of \ prepared \ infusion \ (micrograms/mL)}$ 

## Continuous intravenous infusion (other than for PPH)

Preparation of a 2000 nanograms/mL solution

- 1. Reconstitute each 0.5-mg vial with approximately 10 mL of the provided solvent and shake gently until the powder has dissolved.
- 2. Withdraw the entire contents of the drug vial and inject into the residue of the 50-mL solvent vial.
- 3. Mix well to produce a concentrated solution containing 10000 nanograms/mL.
- 4. Withdraw  $50\,mL$  from a  $250\,mL$  NaCl 0.9% infusion bag and discard.
- 5. Withdraw 50 mL epoprostenol solution from the vial.
- 6. Attach the filter provided to the syringe and using firm but not excessive pressure transfer the concentrated solution into the prepared infusion bag of NaCl 0.9% (it takes about 70 seconds to filter 50 mL). Discard the filter unit.
- 7. Mix well to produce a solution containing 2000 nanograms/mL.
- 8. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

Give by IV infusion using a volumetric infusion device or syringe pump at the specified rate (see Table E3).

Fluid restriction: the concentrated solution may be given undiluted.

| Table E3        | Epoprostenol rate of infusion using a 2000 nanograms/mL solution |                           |     |      |      |

# Additional information

| Common and serious<br>undesirable effects | Immediate: LBP, †pulse, arrhythmia, nausea, vomiting.<br>Injection/infusion-related: Local: Reddening and pain at the infusion site.<br>Extravasation causes tissue damage.<br>Other: Sepsis, septicaemia (mostly related to delivery system), 1platelet<br>count, anxiety, nervousness, headache, facial flushing (seen even in<br>anaesthetised patients), abdominal colic/discomfort, jaw pain. | |
|---|---|---|
| Pharmacokinetics                          | Elimination half-life is 3-5 minutes. The cardiovascular effects during<br>infusion disappear within 30 minutes of the end of administration.                                                                                                                                                                                                                                                      |
| Additional information (continued) |                                                                                                                                                                                                                                                              |  |
|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Significant interactions           | <ul> <li>The following may ↑epoprostenol levels or effect (or ↑side-effects): other anticoagulants or antiplatelet agents, other vasodilators.</li> <li>Epoprostenol may reduce the thrombolytic efficacy of tissue plasminogen activator (t-PA).</li> </ul> |  |
| Action in case of overdose         | Reduce the dose or discontinue the infusion and initiate appropriate supportive measures as necessary, e.g. plasma volume expansion.                                                                                                                         |  |
|                                    |                                                                                                                                                                                                                                                              |  |

| Risk rating: <b>RED</b> | Score = 7<br>High-risk product: Risk-reduction strategies are required to minimise these risks. |

# **Bibliography**

SPC Flolan 0.5 mg injection (accessed 31 March 2010). SPC Flolan 1.5 mg injection (accessed 31 March 2010).

# **Eptifibatide**

#### 2 mg/mL solution in 10-mL vials; 0.75 mg/mL solution in 100-mL vials

- Eptifibatide is an antiplatelet drug that reversibly inhibits binding of fibrinogen, von Willebrand factor, and other adhesive molecules to the glycoprotein IIb/IIIa receptor of platelets.
- It is used, usually in combination with aspirin and heparin, in the management of unstable angina and in patients undergoing coronary angioplasty and coronary artery stenting.

#### **Pre-treatment checks**

- Avoid in abnormal bleeding within 30 days, major surgery or severe trauma within 6 weeks, stroke within last 30 days or any history of haemorrhagic stroke, intracranial disease (aneurysm, neoplasm or arteriovenous malformation), severe *†BP*, haemorrhagic diathesis, *†PT* or INR, thrombocytopenia, significant hepatic impairment; breast feeding.
- · Caution in renal impairment.
- The number of vascular punctures and IM injections should be minimised during the treatment.
- IV access should only be obtained at compressible sites of the body.
- All vascular puncture sites should be documented and closely monitored (caution if there is puncture of a non-compressible vessel within 24 hours).
- The use of urinary catheters, nasotracheal intubation and nasogastric tubes should be critically considered before commencing therapy.

Biochemical and other tests (not all are necessary in an emergency situation)

| ACT            | FBC (including platelets, Hb and haematocrit) |
|----------------|-----------------------------------------------|
| APTT           | LFTs                                          |
| Blood pressure | Prothrombin time                              |
| Bodyweight     | Renal function: U, Cr, CrCl (or eGFR)         |

#### Dose

**Unstable angina or non-Q-wave MI**: 180 micrograms/kg by IV injection as soon as possible after diagnosis, followed by 2 micrograms/kg/minute by IV infusion for up to 72 hours, until initiation of CABG surgery, or until discharge from the hospital (whichever occurs first).

- If PCI is performed during eptifibatide therapy, continue the infusion for 20–24 hours post PCI for an overall maximum duration of therapy of 96 hours.
- If emergency or urgent cardiac surgery is required during the infusion, terminate the eptifibatide immediately.
- If the patient requires semi-elective surgery, stop the infusion at an appropriate time to allow time for platelet function to return towards normal.

#### Concomitant therapy with unfractionated heparin in unstable angina or non-Q-wave MI:

- Patients  $\geq$ 70 kg: 5000 units by IV injection, followed by 1000 units/hour by IV infusion.
- Patients <70 kg, 60 units/kg by IV injection, followed by 12 units/kg/hour by IV infusion.

Dose in renal impairment: adjusted according to creatinine clearance,

- CrCl 30–50 mL/minute: IV injection dose as in normal renal function, IV infusion dose 1 microgram/kg/minute for the duration of therapy.
- CrCl <30 mL/minute: do not use.

**Dose in hepatic impairment:** contraindicated in clinically significant hepatic impairment.

#### Intravenous injection

Preparation and administration

- 1. Using the 2 mg/mL strength, withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 1-2 minutes.

#### **Continuous intravenous infusion**

- 1. The 0.75 mg/mL strength is pre-prepared for use.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Spike the vial with a vented infusion set, taking care to centre the spike within the circle on the stopper top.
- 4. Give by IV infusion at the required rate via a volumetric infusion device.

# Ergocalciferol (calciferol, vitamin D<sub>2</sub>)

#### 300 000 units/mL oily solution in 1-mL and 2-mL ampoules

- The term vitamin D is used for a range of closely related sterol compounds including alfacalcidol, calcitriol, colecalciferol and ergocalciferol. Vitamin D compounds possess the property of preventing or curing rickets.
- Ergocalciferol injection is indicated in patients with gastrointestinal, liver or biliary disease associated with malabsorption of vitamin D, resulting in hypophosphataemia, rickets, and osteomalacia.
- Ergocalciferol 1 mg is considered to be equivalent to 40 000 units of vitamin D; however, dose comparisons between the different vitamin D compounds are imperfect and may not truly reflect relative vitamin D activity.

#### **Pre-treatment checks**

- Do not give to patients with *Ca*, including *Ca* of malignancy.
- Avoid use in hypoparathyroidism.
- · Because of the effect on serum Ca, give to patients with renal stones only when benefits outweigh risks.
- For treatment to be effective, patients should be receiving an adequate daily intake of calcium (dietary or prescribed). Phosphate supplements may also be prescribed if appropriate.

#### Biochemical and other tests

Electrolytes: serum Ca,  $PO_4$ Liver function: Alk Phos Renal function: U, Cr, CrCl (or eGFR) (risk of  $\uparrow$ Ca in renal impairment)

#### Dose

There are reports of ergocalciferol injections being given daily, weekly, monthly, every 2 months or even annually. However, as the duration of action of ergocalciferol injection is approximately 2 months, one option is to give 300 000 units and review Ca and  $PO_4$  levels at 8 weeks. The dose can then be repeated if necessary.

Doses should not normally exceed 40 000 units/day for adults.

# 310 | Ergocalciferol

# Intramuscular injection

# Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

# Additional information

| Common and serious<br>undesirable effects | ↑Ca (persistent constipation or diarrhoea, constant headache, vertigo, loss of appetite, polyuria, thirst, sweating), rash.                                                                                                                                                                                           |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pharmacokinetics                          | There is a lag of 10-24 hours between administration of ergocalciferol and initiation of its action in the body. Maximum effects occur about 4 weeks after administration and the duration of action can be $\geq 2$ months. Ergocalciferol is hydroxylated in the liver and further metabolism occurs in the kidney. |
| Significant interactions                  | No significant interactions.                                                                                                                                                                                                                                                                                          |

(continued)

| Additional information (continued) |                                                                                                                                                                                  |  |  |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|
| Action in case of overdose         | Stop treatment if †Ca develops. However, effects can persist for more than 2 months after ergocalciferol treatment ceases. In severe †Ca give supportive therapy as appropriate. |  |  |
| Counselling                        | Advise to report symptoms of †Ca: persistent constipation or diarrhoea, constant headache, vertigo, loss of appetite, polyuria, thirst, sweating.                                |  |  |
|                                    |                                                                                                                                                                                  |  |  |

# Ertapenem

#### 1-g dry powder vials

- Ertapenem sodium is a carbapenem beta-lactam antibacterial.
- It is used in the treatment of susceptible infections including intra-abdominal infections, acute gynaecological infections, urinary tract infections, skin and skin structure infections (including diabetic foot infections), community-acquired pneumonia and prophylactically in colorectal surgery.
- Doses are expressed in terms of base: Ertapenem  $1 g \cong 1.04 g$  ertapenem sodium.

#### **Pre-treatment checks**

 Do not give if there is known hypersensitivity to any carbapenem antibacterial agent or previous immediate hypersensitivity reaction to penicillins or cephalosporins.

#### **Biochemical tests**

FBC LFTs Renal function: U, Cr, CrCl (or eGFR)

# 312 | Ertapenem

# Dose

Standard dose: 1 g by IV infusion daily.

**Surgical prophylaxis:** 1 g by IV infusion within 1 hour before the start of surgery. Check local policies.

Dose in renal impairment: adjusted according to creatinine clearance:<sup>1</sup>

- CrCl 10-30 mL/minute: 500 mg-1 g daily.
- CrCl <10 mL/minute: 500 mg daily or 1 g three times a week.

#### Intermittent intravenous infusion

Preparation and administration

Ertapenem is incompatible with Gluc 5%, Gluc-NaCl, Hartmann's, Ringer's.

- 1. Reconstitute each 1-g vial with 10 mL WFI or NaCl 0.9% to produce a 100 mg/mL solution. Shake well.
- 2. Withdraw the required dose and add to  $50\,\text{mL}$  NaCl 0.9% (final concentration must be no more than  $20\,\text{mg/mL}$ ).
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 30 minutes.

#### **Technical information** Incompatible with Ertapenem is incompatible with Gluc 5%, Gluc-NaCl, Hartmann's, Ringer's. Anidulafungin, mannitol, sodium bicarbonate. Compatible with Flush: NaCl 0.9% Solutions: WFI, NaCl 0.9% (including added KCl) Y-site: Dextran 40, dextran 70 7.5 pН Sodium content 6 mmol/1-g vial Store below 25°C in original packaging. Storage Displacement value Negligible Stability after preparation From a microbiological point of view, should be used immediately; however. Prepared infusions may be stored at 2-8°C and infused (at room temperature) within 24 hours. • Vials reconstituted for IM injection should be used within 1 hour.

| Monitoring                                        |                                                                                                                                                                                                              |                                                                                                                                                                                                                                                                   |  |

# Bibliography

SPC INVANZ 1 g powder for concentrate for solution for infusion (accessed 17 March 2009).

# Erythromycin lactobionate

#### 1-g dry powder vials

- Erythromycin is a macrolide antibacterial with a broad spectrum of activity.
- It may be used in the treatment of a wide range of infections caused by susceptible organisms including: *Bacillus anthracis, Listeria monocytogenes, Clostridium* spp., *Neisseria meningitidis, Neisseria gonorrhoeae* and *Legionella* spp.
- It is given by IV infusion where high blood levels are required or when the oral route is compromised. Erythromycin was formerly given by IM injection, but such injections are painful and result in unpredictable levels.
- Erythromycin also stimulates gut motility apparently by acting as a motilin receptor agonist. It is
  sometimes used for its prokinetic action in patients with 1GI motility, particularly in critically ill
  patients.
- Doses are expressed in terms of the base: Erythromycin 1 g  $\cong$  1.49 g erythromycin lactobionate.

# **Pre-treatment checks**

- Erythromycin lactobionate **must not** be given by direct IV injection (risk of fatal ventricular arrhythmias).
- · Contraindicated in patients with known hypersensitivity to macrolide antibiotics.
- · Avoid in acute porphyria.
- Caution if predisposition to QT interval prolongation (including electrolyte disturbances, concomitant use of drugs that prolong QT interval).

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Bodyweight in certain indications | LFTs                                  |
|-----------------------------------|---------------------------------------|
| ECG                               | Renal function: U, Cr, CrCl (or eGFR) |

#### Dose

**Intermittent IV infusion:** 250–500 mg every 6 hours for mild to moderate infections. **Continuous IV infusion:** 25–50 mg/kg per day (up to a maximum of 4 g/day in severe infections). **Prokinetic dose (unlicensed):** 250 mg four times daily has been used.<sup>1</sup> **Dose in renal impairment:** CrCl <10 mL/minute: maximum 2 g daily.<sup>2</sup>

# Intermittent intravenous infusion

#### Preparation and administration

Erythromycin lactobionate is incompatible with Gluc 5% (unless buffered, see below), Gluc-NaCl, Hartmann's and Ringer's.

- 1. Reconstitute each vial with 20 mL WFI and shake vigorously to produce a solution containing 50 mg/mL.
- 2. Withdraw the required dose and add to a minimum of 100 mL NaCl 0.9% to give a solution containing 1–5 mg/mL. Mix well.
- 3. The solution should be clear and colourless to very pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 60 minutes. Give more slowly in patients with risk factors or previous history of arrhythmias.

# **Continuous intravenous infusion**

- 1. Reconstitute each 1-g vial with 20 mL WFI and shake vigorously to produce a solution containing 50 mg/mL.
- Withdraw the required dose and add to a suitable volume of NaCl 0.9% to give a final concentration of about 1 mg/mL. Mix well. Concentrations up to 5 mg/mL have been used but may <sup>†</sup>venous irritation.
- The solution should be clear and colourless to very pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion. Prepare a fresh infusion bag at least every 24 hours if required.

Pharmacokinetics

Elimination half-life in normal renal function is about 2 hours. In severe impairment it may be 4-7 hours.

(continued)

# Erythropoietins (epoetins, recombinant human erythropoietins)

- Erythropoietin is a glycosylated protein hormone and a hematopoietic growth factor secreted primarily by the kidneys, which regulates erythropoiesis.
- Epoetins (recombinant human erythropoietins) are used to treat symptomatic anaemia associated with
  erythropoietin deficiency in chronic renal failure, to \u03c6 yield of autologous blood in normal individuals
  and to shorten the period of symptomatic anaemia in patients receiving cytotoxic chemotherapy.
- There are five forms currently marketed in the UK: epoetin alfa, epoetin beta, epoetin zeta, darbepoetin alfa and methoxy polyethylene glycol-epoetin beta (pegzerepoetin alfa).
- The scope of this monograph is to describe the monitoring requirements that are required for them. Individual dosing regimens vary widely and standard literature sources should be used to check these.

#### MHRA/CHM advice (December 2007, July 2008)

Overcorrection of Hb concentration in patients with chronic kidney disease (CKD) may  $\uparrow$ risk of death and serious cardiovascular events, and in patients with cancer may  $\uparrow$ risk of death and thrombosis and related complications:

- Patients should not be treated with erythropoietins (within the licensed indications) in CKD or cancer unless symptoms of anaemia are present.
- Hb concentration should be maintained within the range 10–12 g/dL (Hb  $>\!12$  g/dL should be avoided).
- The aim of treatment is to relieve symptoms of anaemia, and in patients with CKD to avoid the need for blood transfusion; the Hb concentration should not be increased beyond that which provides adequate control of symptoms.
- Erythropoietins licensed for treatment for symptomatic anaemia associated with cancer are licensed **only** for patients who are receiving chemotherapy. The decision to treat should be based on assessment of benefits and risks and in some cases blood transfusion may be a preferred option.

#### **Pre-treatment checks**

- Contraindicated in poorly controlled *†BP*, in patients with advanced head and neck cancer receiving radiation therapy, and in breast feeding.
- · Caution advised in hepatic impairment, sickle-cell anaemia, epilepsy and pregnancy.
- The needle cover of some formulations of pre-filled syringes may contain dry natural rubber (latex derivative), which may cause allergic reactions.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure Bodyweight FBC (any deficiency in iron status should be identified and corrected before treatment in order to ensure effective erythropoiesis) LFTs

#### Dose

Consult specific product literature for individual drugs.

# **Esmolol hydrochloride**

#### $10\,mg/mL$ solution in 10-mL vials and 250-mL infusion bags

- Esmolol hydrochloride is a cardioselective beta-adrenoceptor blocker with a very short duration of action.

#### **Pre-treatment checks**

- Use with caution in patients with a history of wheezing or asthma and peripheral circulatory conditions.
- Treatment should be avoided in sick sinus syndrome, heart block greater than first degree, cardiogenic shock and overt heart failure, and hypersensitivity to the substance.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Blood pressure | Heart rate                            |
|----------------|---------------------------------------|
| Bodyweight     | Renal function: U, Cr, CrCl (or eGFR) |

#### Dose

**Supraventricular tachyarrhythmias:** 50–200 micrograms/kg/minute. Dose must be individualised by titration as described in Table E4, in which each step consists of a loading dose followed by a maintenance dose. As the desired end point is approached, omit the loading dose and increase the interval between titration steps from 5 to 10 minutes.

| If adequate response                                  | Maintain infusion rate of 150 micrograms/kg/minute                    |                                        |  |
| Inadequate response                                   | 500 micrograms/kg over 1 minute                                       | 200 micrograms/kg/minute for 4 minutes |  |
| If adequate response                                  | Maintain infusion rate of 200 micrograms/kg/minute for up to 48 hours |                                        |  |

# Table E4 Esmolol loading and maintenance dose regimens

When transferring a patient to another antiarrhythmic drug, e.g. verapamil or digoxin, the infusion rate of esmolol hydrochloride is reduced by 50% 30 minutes after starting the alternative drug, and may be stopped 1 hour after the second dose of that drug if it is effective.

#### Loading dose calculation:

• 500 micrograms/kg = bodyweight (kg) divided by 20 = dose in mL of esmolol 10 mg/mL.

For example, for a 70-kg individual, dose = 70/20 = 3.5 mL esmolol 10 mg/mL.

#### Maintenance dose calculation:

- 50 micrograms/kg/minute = bodyweight (kg)  $\times$  60/200 = dose in mL of esmolol 10 mg/mL/hour.
- 100 micrograms/kg/minute = bodyweight (kg) × 60/100 = dose in mL of esmolol 10 mg/mL/hour.
- \* 150 micrograms/kg/minute = bodyweight (kg)  $\times$  60/66 = dose in mL of esmolol 10 mg/mL/hour.
- \* 200 micrograms/kg/minute = bodyweight (kg)  $\times$  60/50 = dose in mL of esmolol 10 mg/mL/hour.
- 250 micrograms/kg/minute = bodyweight (kg)  $\times$  60/40 = dose in mL of esmolol 10 mg/mL/hour.
- 300 micrograms/kg/minute = bodyweight (kg) × 60/33 = dose in mL of esmolol 10 mg/mL/hour.

#### Control of perioperative hypertension and/or tachycardia:

- During anaesthesia: a loading dose of 80 mg (8 mL) by IV injection over 15–30 seconds followed by 150 micrograms/kg/minute by IV infusion, increased as necessary up to 300 micrograms/kg/ minute (see dose calculation above).
- On waking from anaesthesia: 500 micrograms/kg/minute for 4 minutes; followed by 300 micrograms/kg/minute by IV infusion as required. Alternatively if time for titration is available, dose as for supraventricular tachyarrhythmias as above.

# Intravenous injection (for loading doses)

- 1. Withdraw the required dose (see above for calculation).
- The solution should be clear and colourless to light yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection at the rate specified above for the particular indication.

# Intravenous infusion (for maintenance doses)

### Preparation and administration

- 1. Esmolol hydrochloride is available as pre-prepared infusion solution containing 10 mg/mL in a 250-mL infusion bag.
- 2. The solution should be clear and colourless to light yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion via a volumetric infusion device at rate appropriate to dosing regimen (see above for calculation).

# **Esomeprazole**

#### 40-mg dry powder vials

- Esomeprazole sodium is a proton pump inhibitor (PPI), being the S-isomer of omeprazole.
- It is used to prevent re-bleeding following therapeutic endoscopy for acute bleeding gastric or duodenal ulcers.
- It may also be used IV when the oral route is temporarily unavailable, to treat conditions where inhibition of gastric acid secretion may be beneficial: treatment and prevention of gastric and duodenal ulcers, gastro-oesophageal reflux disease (GORD) and Zollinger–Ellison syndrome.
- Doses are expressed in terms of esomeprazole: Esomeprazole 40 mg ≅ 42.6 mg esomeprazole sodium.

#### **Pre-treatment checks**

- PPIs may mask symptoms of gastric cancer (and delay diagnosis); particular care is required in those whose symptoms change and in those who are middle-aged or older.
- Caution in severe renal impairment (due to lack of experience).

#### Biochemical and other tests

LFTs Renal function: U, Cr, CrCl (or eGFR)

#### Dose

**Prevention of re-bleeding of gastric or duodenal ulcers:** initially 80 mg by IV infusion over 30 minutes, followed by 8 mg/hour by continuous IV infusion for 72 hours. **GORD:** 40 mg daily.

Symptomatic reflux disease without oesophagitis, treatment of NSAID-associated gastric ulcer, prevention of NSAID-associated gastric or duodenal ulcer: 20 mg daily. Dose in hepatic impairment: severe impairment (Child–Pugh Class C) maximum 20 mg daily.

#### Intravenous injection

#### Preparation and administration

- 1. Reconstitute each vial with 5 mL NaCl 0.9% to give a solution containing 40 mg/5 mL.
- 2. Withdraw the required dose.
- The solution should be clear and colourless to very slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over at least 3 minutes.

#### Intermittent intravenous infusion

#### Preparation and administration

- 1. Reconstitute each vial with 5 mL NaCl 0.9% to give a solution containing 40 mg/5 mL.
- 2. Withdraw the required dose and add to 50-100 mL NaCl 0.9%.
- The solution should be clear and colourless to very slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 10-30 minutes (30 minutes for 80-mg dose).

# **Continuous intravenous infusion**

- 1. Reconstitute each vial with 5 mL NaCl 0.9%.
- 2. Add 80 mg to 100 mL NaCl 0.9% or other compatible infusion fluid (but see Stability below).
- 3. The solution should be clear and colourless to very slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 10 hours (8 mg/hour).

# Bibliography

SPC Nexium IV (accessed 28 September 2009).

# Etanercept

# 25-mg dry powder vials with solvent; 25-mg and 50-mg pre-filled syringes; 50-mg pre-filled pens

- Etanercept is a cytokine modulator; it must only be used under specialist supervision.
- It is licensed for use in the treatment of rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis and plaque psoriasis.
- In the UK, if treatment is for any rheumatological condition other than those listed above, the
  patient should be entered on the British Society of Rheumatology's Biologics Register.<sup>1</sup>
- Etanercept has been assessed by NICE and in the UK should be used in accordance with the appropriate guidance.

#### **Pre-treatment checks**

- Do not give if the patient has any active infections including chronic or localised infections; record
  results on a patient alert card. There is a risk of false-negative tuberculin skin test results in patients
  who are severely ill or immunocompromised.
- Monitor patients for hepatitis B virus: reactivation of hepatitis B has occurred in patients who are carriers.
- Caution in congestive heart failure, which may worsen.
- Caution should be exercised when using in patients with demyelinating CNS disorders since there is a risk of exacerbating clinical symptoms.
- · Caution in patients with moderate to severe alcoholic hepatitis.

#### Dose

**Rheumatoid arthritis, psoriatic arthritis, ankylosing spondylitis**: 25 mg by SC injection twice weekly or 50 mg by SC injection once weekly.

**Plaque psoriasis:** 25 mg by SC injection twice weekly or 50 mg by SC injection once weekly. Alternatively, 50 mg may be given twice weekly for a maximum of 12 weeks followed, if required, by 25 mg twice weekly or 50 mg once weekly. The usual total treatment duration is 24 weeks.

# **Subcutaneous injection**

#### Preparation and administration

- 1. **For dry powder vials:** Slowly add 1 mL WFI (supplied) to the vial and swirl gently to minimise foaming until all the powder has completely dissolved. The solution then contains 25 mg/mL. If the powder has not all dissolved within 10 minutes then discard the vial.
- For all presentations: Either withdraw the required dose or select the appropriate pre-filled syringe. (If using the MYCLIC pre-filled pen, follow detailed instructions in the package insert.)
- 3. The solution should be clear and colourless to pale yellow. Inspect visually to make sure there are no lumps, flakes or particles.
- 4. Allow the injection to reach room temperature (approximately 15–30 minutes). Do not remove the needle cover on pre-filled syringes until room temperature is reached.
- 5. Give by SC injection into the thigh, abdomen, or upper arm. Rotate injection sites for subsequent injections.

# Ethanolamine oleate (monoethanolamine oleate)

#### 5% solution in 2-mL and 5-mL ampoules

- Ethanolamine oleate is a sclerosing agent that, when injected into a vein, irritates the endothelium, resulting in thrombus formation and occlusion of the vein. Fibrous tissue develops to permanently obliterate the occluded vessel.
- It is used in the local treatment of small uncomplicated varicose veins in the lower extremities.
- · It has also been used as a sclerosing agent in oesophageal varices (unlicensed indication).

#### **Pre-treatment checks**

- Do not give in local or systemic infection, marked arterial or cardiac disease or severe renal impairment.
- Contraindicated if the patient is unable to walk; in acute phlebitis, obese legs, superficial thrombophlebitis and deep vein thrombosis in the region of the varicose veins.
- Do not use if there is a history of uncontrolled metabolic disorders, e.g. diabetes mellitus.
- Do not use if the patient is taking oral contraceptives.

#### Biochemical and other tests

Body temperature FBC Renal function: U, Cr, CrCl (or eGFR)

#### Dose

**Sclerosis of varicose veins:** a total dose of 2–5 mL is slowly injected directly into the empty isolated sections of varicose vein in divided doses between three or four sites. Dose can be repeated at weekly intervals to achieve required clinical result.

**Sclerosis of oesophageal varices (unlicensed indication):** a dose of 1.5–5 mL is injected per varix, up to a maximum of 20 mL per treatment session. Treatment may be given in the initial management of bleeding varices, then repeated at intervals (usually after 1 week, 6 weeks, 3 months and 6 months as indicated) until all varices are occluded.

# Local injection into vein

- 1. Withdraw the required volume.
- Slowly inject the prepared volume of solution into affected section(s) of varicose vein, or into oesophageal varix/varices, taking care not to leak solution into surrounding tissue (extravasation may cause necrosis of tissues, and there is a risk of sloughing and ulceration).

# Exenatide

#### 5 micrograms/dose and 10 micrograms/dose solution in pre-filled pen

- Exenatide is a synthetic form of exendin-4, a 39-amino-acid peptide isolated from the venom of the Gila monster lizard. It is an incretin mimetic that †insulin secretion, ↓glucagon secretion, and slows gastric emptying.
- It is used for the treatment of type 2 diabetes mellitus in combination with metformin and/or
  a sulfonylurea, in patients who have not achieved adequate glycaemic control with these drugs
  alone or in combination. It is also licensed for use with glitazones (with or without other oral
  agents) in the USA.

#### **Pre-treatment checks**

- · Do not use in type 1 diabetes mellitus or for the treatment of diabetic ketoacidosis.
- Not licensed in combination with insulin in type 2 diabetes.
- Do not use in severe renal impairment (CrCl or eGFR <30 mL/minute).
- Avoid in severe gastrointestinal disease (including gastroparesis) because of GI side-effects.
- Avoid in pregnancy and breast feeding insulin is a safe alternative.
- Consider reducing the dose of sulfonylurea when starting therapy.
- Ensure that the patient reads and understands the user manual.

#### Biochemical and other tests

HbA<sub>1c</sub> Renal function: U, Cr, CrCl (or eGFR)

#### Dose

Initiate at 5 micrograms twice daily by SC injection for at least 1 month, in order to improve tolerability. The dose can then be increased to 10 micrograms twice daily to further improve glycae-mic control.

- Give the dose 60 minutes or less before the two main meals of the day (at least 6 hours apart).
- Exenatide **must not** be injected after a meal.

### **Subcutaneous injection**

Exenatide must not be injected after a meal.

- 1. The solution should be clear and colourless, do not use if cloudy or discoloured or if particles are present.
- 2. Dial up the dose according to the pen-user manual (see package insert).
- 3. Give by SC injection into the upper outer thigh, abdomen or upper arm. Remove the needle after use and discard according to local guidelines. Although not specifically recommended by the manufacturer, it would be wise to vary the site of the injection.

# Fentanyl

#### 50 micrograms/mL solution in 2-mL and 10-mL ampoules

- Fentanyl citrate is a potent opioid analgesic chemically related to pethidine.
- It is used parenterally at low doses to provide analgesia during surgery and at higher doses as an analgesic and respiratory depressant during assisted ventilation. It may also be used to provide pain relief in other situations.
- Doses are expressed in terms of the base: Fentanyl 100 micrograms ≅ 157 micrograms fentanyl citrate.

#### **Pre-treatment checks**

- · Avoid in patients with respiratory depression or obstructive airways disease.
- Do not give with monoamine oxidase inhibitors or within 2 weeks of their discontinuation.
- Only give in an environment where the airway can be controlled. Resuscitation equipment should be available.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Bodyweight (use IBW if overweight, to avoid excessive dosing) Respiratory rate

#### Dose

The analgesic/respiratory depressant dose used depends on whether the patient has spontaneous respiration or has assisted ventilation.

**Spontaneous respiration**: initially 50–100 micrograms by IV injection followed by further doses of 50 micrograms if required.

- Maximum initial dose is 200 micrograms on specialist advice only.
- Alternatively, give 50-80 nanograms/kg/minute by IV infusion adjusted according to response.

**Assisted respiration**: initially 300–3500 micrograms followed by further doses of 100–200 micrograms adjusted according to response.

- Alternatively, initially give 1 microgram/kg/minute by IV infusion for 10 minutes followed by 100 nanograms/kg/minute adjusted according to response.
- Higher infusion rates up to 3 micrograms/kg/minute have been used in cardiac surgery.
- Stop infusion about 40 minutes before end of surgery unless it is planned to ventilate postoperatively.

**Premedication**: 50–100 micrograms (1–2 mL) may be given by IM injection 45 minutes before induction of anaesthesia.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV injection over 1-2 minutes.
- 4. Close monitoring of respiratory rate and consciousness recommended.

# Intravenous infusion

- 1. Withdraw the required dose and add to a suitable volume of compatible infusion solution.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

# 336 | Fentanyl

- 3. Give by IV infusion via a volumetric infusion device or syringe pump at a rate appropriate to the clinical condition of the patient. Adjust dose to clinical response.
- 4. Close monitoring of respiratory rate and consciousness recommended.

# Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IM injection.
- 4. Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving initial dose, especially elderly patients or those of low bodyweight.

# Monitoring

Close monitoring of respiratory rate and consciousness is recommended for 30 minutes in patients receiving initial dose, especially elderly patients or those of low bodyweight.

IBER Score = 5 Moderate-risk product: Risk-reduction strategies are recommended.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Sublimaze (accessed 12 December 2008).

# Filgrastim (G-CSF, r-metHuCSF)

#### 300 micrograms/mL solution in 1-mL and 1.6-mL vials

#### 300 micrograms/0.5 mL and 480 micrograms/0.5 mL solution in 0.5-mL pre-filled syringes

- Filgrastim is recombinant methionyl human granulocyte-colony stimulating factor (G-CSF), produced using r-DNA technology in *E. coli*. It acts primarily on neutrophil precursors to increase neutrophil levels.
- It is used to treat or prevent neutropenia in patients receiving myelosuppressive cancer chemotherapy (except in chronic myeloid leukaemia and myelodysplastic syndromes), to reduce the duration of neutropenia in patients undergoing bone marrow transplantation and to mobilise peripheral blood progenitor cells in blood stem cell transplantation.
- Doses are expressed in micrograms or units (micrograms are used throughout this monograph): Filgrastim 10 micrograms ≡1 million units.

#### **Pre-treatment checks**

- Prior to commencing treatment for neutropenia, exclude possible causes of transient neutropenia, e.g. viral infections.
- Do not use in severe congenital neutropenia (Kostmann's syndrome) with abnormal cytogenetics.
- Caution in secondary acute myeloid leukaemia, sickle-cell disease; monitor spleen size (risk of rupture); existing osteoporotic bone disease.
- If the patient is receiving cytotoxic chemotherapy, ensure that the first dose of filgrastim is not
  administered in the first 24 hours following the completion of the cycle of chemotherapy.

#### Biochemical and other tests

| Blood pressure                       | FBC including differential white cell and platelet |
|--------------------------------------|----------------------------------------------------|
| Bodyweight (for certain indications) | counts                                             |
|                                      | LFTs                                               |

#### Dose

**Cytotoxic-induced neutropenia:** 5 micrograms/kg once daily by SC injection (preferred route), or by IV infusion. The first dose should be given a minimum of 24 hours after cytotoxic therapy and is usually continued until neutrophil count is within the normal range.

**Myeloablative therapy followed by bone marrow transplantation:** 10 micrograms/kg daily given either by a 30-minute or 24-hour IV infusion, or by a 24-hour SC infusion. The first dose should be given a minimum of 24 hours after cytotoxic therapy and is further titrated according to patient response (see product literature).

**Mobilisation of peripheral blood progenitor cells for autologous infusion:** if filgrastim is being used alone, 10 micrograms/kg daily given by a 24-hour SC infusion or as a single daily SC injection for 5–7 consecutive days until leucopheresis is complete (see product literature).

**Mobilisation of peripheral blood progenitor cells in normal donors for allogeneic infusion:** 10 micrograms/kg daily by SC injection for 4–5 consecutive days (for timing of leucopheresis see product literature).

Severe chronic neutropenia, congenital: initially 12 micrograms/kg daily by SC injection as a single dose or divided doses and adjusted according to response. Maintenance dose should be the minimum required to maintain neutrophil count (see product literature).

**Severe chronic neutropenia, idiopathic or cyclic:** initially 5 micrograms/kg daily by SC injection as a single dose or divided doses and adjusted according to response. Maintenance dose should be the minimum required to maintain neutrophil count (see product literature).

**Persistent neutropenia in HIV infection:** initially 1 microgram/kg daily by SC injection titrated up to 4 micrograms/kg daily according to response. Maintenance dose should be the minimum required to maintain neutrophil count (see product literature).

# **Subcutaneous injection**

#### Preparation and administration

- 1. Withdraw the required dose from a vial using a needle suitable for SC injection, or select an appropriately sized pre-filled syringe.
- 2. Give by SC injection. Rotate injection sites for subsequent injections.

# Subcutaneous infusion

Preparation and administration

Filgrastim is incompatible with NaCl 0.9%.

1. Withdraw the required dose and add to a suitable volume of Gluc 5%, ensuring that the final concentration is 15 micrograms/mL or more.\*

- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give as a continuous SC infusion, preparing a fresh infusion every 24 hours.

\*Stability is concentration dependent: if filgrastim concentration is <15 micrograms/mL then human serum albumin must be added to produce a final albumin concentration of 2 mg/mL.

#### Intermittent intravenous infusion

Preparation and administration

Filgrastim is incompatible with NaCl 0.9%.

- 1. Withdraw the required dose and add to a suitable volume of Gluc 5%, ensuring that the final concentration is 15 micrograms/mL or more.\*
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 30 minutes.

\*Stability is concentration dependent: if filgrastim concentration is <15 micrograms/mL then human serum albumin must be added to produce a final albumin concentration of 2 mg/mL.

#### **Continuous intravenous infusion**

Preparation and administration

Filgrastim is incompatible with NaCl 0.9%.

- 1. Withdraw the required dose and add to a suitable volume of Gluc 5%, ensuring that the final concentration is 15 micrograms/mL or more.\* Mix well.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by continuous IV infusion via a volumetric infusion device. Prepare a fresh infusion at least every 24 hours.

\*Stability is concentration dependent: if filgrastim concentration is <15 micrograms/mL then human serum albumin must be added to produce a final albumin concentration of 2 mg/mL.

| Action in case of overdose                                                        | Effects not established. Discontinuation of treatment usually results in a 50% decrease in circulating neutrophils within 1-2 days, returning to normal levels in 1-7 days.                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                              |  |
| Counselling                                                                       | Training in aseptic technique and administration if self-administering.<br>Safe disposal of needles, syringes and unused drug.                                                                                                                                                                                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                              |  |
#### 342 | Filgrastim | Flecainide acetate

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Neupogen (accessed 22 September 2009).

# Flecainide acetate

#### 10 mg/mL solution in 15-mL ampoules

- · Flecainide is a class 1 (membrane-stabilising) antiarrhythmic agent.
- It is used IV for rapid control of severe symptomatic ventricular arrhythmias such as sustained ventricular tachycardia and severe symptomatic supraventricular arrhythmias.

#### **Pre-treatment checks**

- Contraindicated in the following: heart failure; abnormal left ventricular function; history of
  myocardial infarction and either asymptomatic ventricular ectopics or asymptomatic non-sustained ventricular tachycardia; long-standing atrial fibrillation where conversion to sinus rhythm
  is not attempted; haemodynamically significant valvular heart disease. Avoid in sinus node dysfunction, atrial conduction defects, second-degree or greater AV block, bundle branch block or
  distal block unless pacing rescue is available.
- Caution in patients with a history of cardiac failure, who may become decompensated during the
  administration (in such patients it is recommended that the initial dose is given over 30 minutes).
- Caution also in patients with pacemakers (especially those who may be pacemaker dependent because the stimulation threshold may rise appreciably), in atrial fibrillation following heart surgery, and in elderly patients (accumulation may occur).
- ECG monitoring and resuscitation facilities must be available.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Bodyweight                | LFTs                  |
|---------------------------|-----------------------|
| ECG                       | Renal function: U, Cr |
| Electrolytes: serum Na, K |                       |

#### Dose

**Initial dose:** 2 mg/kg (maximum 150 mg) given by IV injection over at least 10 minutes, or as a small-volume infusion in Gluc 5% over 10–30 minutes. This may be followed by IV infusion if appropriate.

**Intravenous infusion:** 1.5 mg/kg/hour for the first hour, followed by 100–250 micrograms/kg/ hour for a maximum of 24 hours.

- The cumulative dose in the first 24 hours should not exceed 600 mg.
- Oral therapy should be started as soon as possible, the first oral dose being given as the infusion is stopped.

**Dose in renal impairment**: if CrCl <35 mL/minute, reduce each of the above doses by half. **Dose in hepatic impairment**: avoid (or reduce dose) in severe liver disease.

#### **Initial dose**

- 1. Withdraw the required dose. Use undiluted or dilute with 20-100 mL Gluc 5%.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over a minimum of 10 minutes or by small-volume infusion over 10–30 minutes.

## **Continuous intravenous infusion**

- 1. Withdraw the required dose and add to a suitable volume of Gluc 5%. Mix well.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion as specified above for a maximum of 24 hours.

| Technical information                                                      |                                                                                                                                                 |                                                                                                                                                                                                                                                           |  |

SPC Tambocor injection (accessed 1 October 2009).

# Flucloxacillin (floxacillin)

#### 250-mg, 500-mg, 1-g dry powder vials

- Flucloxacillin sodium is a penicillin with a mode of action similar to that of benzylpenicillin, but it is resistant to staphylococcal penicillinase.
- It is particularly useful in infections caused by staphylococci resistant to benzylpenicillin. These
  include bone and joint infections, endocarditis and soft-tissue infections.
- Dose are expressed in terms of flucloxacillin: Flucloxacillin 1 g  $\equiv$  1.09 g flucloxacillin sodium.

#### **Pre-treatment checks**

- Do not give if there is known hypersensitivity to penicillin.
- Avoid in patients with a history of hepatic dysfunction associated with flucloxacillin.
- Flucloxacillin is considered unsafe in porphyria (associated with acute attacks).

#### Biochemical and other tests (not all are necessary in an emergency situation)

Bodyweight in certain indicationsLFTsFBCRenal function: U, Cr, CrCl (or eGFR)

#### Dose

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line with a compatible solution between drugs.

Standard dose: 250 mg-2 g by IM or IV injection or IV infusion every 6 hours.

Osteomyelitis: 2 g by IV injection or infusion every 6-8 hours.

**Endocarditis**: bodyweight  $\leq$ 85 kg: 2 g by IV injection or infusion every 6 hours; bodyweight >85 kg: 2 g every 4 hours.

**Surgical prophylaxis**: 1–2g at induction by IV injection or infusion followed by (for high risk procedures), up to four further doses of 500 mg orally or parenterally every 6 hours. Check local policies. **Intrapleural injection**: 250 mg once daily.

Intra-articular injection: 250–500 mg once daily.

Nebulised: 125-250 mg every 6 hours.

Dose in renal impairment: adjusted according to creatinine clearance:1

- CrCl >10 mL/minute: dose as in normal renal function.
- CrCl <10 mL/minute: dose as in normal renal function (maximum total daily dose 4 g).

Dose in hepatic impairment: use with caution (risk of cholestatic jaundice and hepatitis).

#### Intravenous injection

Preparation and administration

See Special handling below.

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line with a compatible solution between drugs.

- 1. Dissolve each 250 mg in 5 mL WFI (i.e. use 10 mL for a 500-mg vial, 20 mL for 1-g vial).
- 2. Withdraw the required dose.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over 3-4 minutes.

## Intermittent intravenous infusion

Preparation and administration

See Special handling below.

If used in combination with an aminoglycoside (e.g. amikacin, gentamicin, tobramycin), preferably administer at a different site. If this is not possible then flush the line with a compatible solution between drugs.

- 1. Reconstitute each 250-mg vial with 5 mL WFI (use 10 mL for each 500-mg vial, 20 mL for each 1-g vial).
- Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually 100 mL NaCl 0.9%).
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 30-60 minutes.

#### Intramuscular injection (maximum dose 500 mg)

Preparation and administration

See Special handling below.

- 1. Reconstitute each 250-mg vial with 1.5 mL WFI (use 2 mL for each 500-mg vial).
- 2. Withdraw the required dose.
- 3. Give by IM injection into a large muscle such as the gluteus or the lateral aspect of the thigh. Rotate injection sites for subsequent injections.

#### Other routes

See Special handling below.

- Intrapleural injection: dissolve 250 mg in 5–10 mL WFI.
- Intra-articular injection: dissolve 250–500 mg in up to 5 mL of WFI. If pain occurs, 0.5% lidocaine may be used for reconstitution (see the Lidocaine monograph for cautions and monitoring)
- Nebulised: dissolve 250 mg in 3 mL of WFI.

#### 348 | Flucloxacillin | Fluconazole

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

## Reference

#### **Bibliography**

SPC Flucloxacillin 500 mg powder for solution for injection or infusion, Wockhardt (accessed 28 September 2009).

# Fluconazole

#### 2 mg/mL solution in 50-mL, 100-mL, 200-mL infusion bags; 25-mL, 100-mL infusion vials

- Fluconazole is a triazole antifungal drug that in sensitive fungi selectively inhibits cytochrome P450-dependent enzymes resulting in impairment of ergosterol synthesis, an essential component of fungal cell membranes.
- It is used IV to treat systemic fungal infections including candidiasis, coccidioidomycosis and cryptococcosis.

#### **Pre-treatment checks**

Do not use in acute porphyria.

Biochemical and other tests (not all are necessary in an emergency situation)

| Electrolytes: serum K | Renal function: U, Cr, CrCl (or eGFR)            |
|-----------------------|--------------------------------------------------|
| FBC                   | Consider baseline ECG (caution in susceptibility |
| LFTs                  | to QT interval prolongation)                     |

#### Dose

**Invasive candidal infections (including candidaemia and disseminated candidiasis) and cryptococcal infections (including meningitis):** 400 mg by IV infusion on first day then 200–400 mg daily; unlicensed doses of 800–1000 mg daily have been used in severe infections with treatment continued according to response (at least 8 weeks for cryptococcal meningitis).

**Prevention of relapse of cryptococcal meningitis in AIDS patients after completion of primary therapy:** 100–200 mg daily by IV infusion (or orally).

**Prevention of fungal infections in immunocompromised patients**: 50–400 mg daily by IV infusion (or orally), adjusted according to risk: 400 mg daily if there is high risk of systemic infections,

e.g. following bone-marrow transplantation. Commence treatment before the anticipated onset of neutropenia and continue for 7 days after the neutrophil count has reached the desirable range.

**Dosing in renal impairment (in patients who will receive multiple doses):** the normal dose is given according to indication on day 1, then the dose is adjusted according to creatinine clearance, i.e.

- CrCl >50 mL/minute dose as in normal renal function.
- CrCl 11-50 mL/minute (no dialysis) 50% of normal dose.
- Patients receiving regular dialysis one normal dose after every dialysis session.

## Intermittent intravenous infusion

#### Preparation and administration

- 1. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV infusion at a rate of 5–10 mL/minute (300–600 mL/hour). In the USA, a maximum infusion rate of 100 mL/hour is recommended.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

#### **Bibliography**

SPC Diflucan capsules 50 mg and 200 mg, powder for oral suspension 50 mg/5 mL and 200 mg/5 mL, intravenous infusion 2 mg/mL (accessed 17 March 2009).

SPC Fluconazole 2 mg/mL intravenous infusion, Hospira UK Ltd (accessed 17 March 2009).

# **Flucytosine**

#### 2.5 g/250 mL (10 mg/mL) solution in infusion bottles

- · Flucytosine is a fluorinated pyrimidine antifungal.
- It is used in the treatment of systemic fungal infections. Because there is a high incidence of
  primary resistance amongst target organisms, it is usually used synergistically with amphotericin
  or fluconazole in the treatment of severe systemic candidiasis and cryptococcal meningitis.

#### **Pre-treatment checks**

Biochemical and other tests (not all are necessary in an emergency situation)

FBC LFTs Renal function: U, Cr, CrCl (or eGFR)

Cultures for sensitivity testing should ideally be taken before treatment and repeated at regular intervals during therapy; however it is not necessary to delay treatment until these test results are known.

#### Dose

Standard dose: 50 mg/kg four times a day by IV infusion, usually for no more than 7 days.

**Patients harbouring extremely sensitive organisms**: 25–37.5 mg/kg by IV infusion four times a day may be sufficient.

**Cryptococcal meningitis (with amphotericin)**: 25 mg/kg daily four times a day by IV infusion for at least 4 months.

Dose in renal impairment: adjusted according to creatinine clearance:

- CrCl >20-40 mL/minute: 50 mg/kg every 12 hours.
- CrCl 10-20 mL/minute: 50 mg/kg every 24 hours.
- CrCl <10 mL/minute: an initial single dose of 50 mg/kg with subsequent doses adjusted according to the serum concentration of the drug (see Monitoring below).

#### Intermittent intravenous infusion

- The infusion is pre-prepared for use. It should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 2. Give the required dose by IV infusion over 20-40 minutes.

## 352 | Flucytosine

| Technical information |                                                                                                                                                                                   |  |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Incompatible with     | Do not mix with other drugs during infusion.                                                                                                                                      |  |

# Additional information

| Common and serious<br>undesirable effects | Nausea, vomiting, diarrhoea and skin rashes may occur and are usually transient. |
|-------------------------------------------|----------------------------------------------------------------------------------|
| Pharmacokinetics                          | Elimination half-life is 3-6 hours in normal renal function.                     |

| Additional information (continued)                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                      |  |
|-------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Significant<br>interactions                                                                           | <ul> <li>The following may ↑flucytosine levels or effect (or ↑side-effects): cytarabine (monitor FBC more frequently); drugs that impair renal function, e.g. amphotericin may ↓flucytosine elimination and ↑toxicity (monitor flucytosine levels and renal function more frequently).</li> <li>Cytarabine may oppose the antifungal effects, or ↓flucytosine (monitor levels) or effect.</li> </ul> |  |
| Action in case of overdose                                                                            | Stop administration and give supportive therapy as appropriate. Haemodialysis produces a rapid fall in the serum concentration.                                                                                                                                                                                                                                                                      |  |
|                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                      |  |
| Risk rating: AMBER                                                                                    | Score = 3<br>Moderate-risk product: Risk-reduction strategies are recommended.                                                                                                                                                                                                                                                                                                                       |  |
|                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                      |  |
| This assessment is based on the full range of preparation and administration options described in the |                                                                                                                                                                                                                                                                                                                                                                                                      |  |

# Bibliography

SPC Ancotil 2.5 g/250 mL solution for infusion (accessed 17 March 2009).

monograph. These may not all be applicable in some clinical situations.

# Flumazenil

#### 100 microgram/mL solution in 5-mL ampoules

- Flumazenil is a benzodiazepine antagonist that acts competitively at CNS benzodiazepine receptors.
- It is used in anaesthesia and intensive care for complete or partial reversal of sedation caused by benzodiazepines.
- · It may also be used to diagnose or treat benzodiazepine toxicity in certain circumstances.

#### **Pre-treatment checks**

- · Avoid in patients with a known hypersensitivity to benzodiazepines.
- Flumazenil is not recommended for use in epileptic patients who have been receiving benzodiazepine treatment for a prolonged time.
- · Use cautiously in alcoholic patients to avoid precipitation of alcohol withdrawal seizures.
- Do not give to patients who have been given a benzodiazepine for control of a potentially lifethreatening situation.
- Caution is required in cases of mixed intoxication with benzodiazepines and tricyclic antidepressants where there are symptoms of severe intoxication with tricyclics, e.g. cardiovascular symptoms (the toxicity of the antidepressants can be masked by the protective benzodiazepine effects).

#### Biochemical and other tests (not all are necessary in an emergency situation)

LFTs Respiratory rate Sedation levels

#### Dose

By IV injection: 200 micrograms over 15 seconds, then 100 micrograms at 60-second intervals if required.

- The usual dose range is 300-600 micrograms.
- The maximum total dose is 1 mg (or 2 mg in intensive care settings).
- If there is no response question the diagnosis.

**By IV infusion**: if drowsiness recurs, give 100–400 micrograms/hour (adjust rate according to response).

**Dose in hepatic impairment**: flumazenil is mainly metabolised in the liver; careful titration is recommended in patients with impaired hepatic function.

#### **Intravenous injection**

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 15 seconds. Injection into a freely running IV infusion line can reduce pain at the injection site.

#### **Continuous intravenous infusion**

- 1. Withdraw the required dose and add to a suitable volume of Gluc 5% or NaCl 0.9%. Mix well.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion at a rate of 100-400 micrograms/hour (adjusted according to response).

# Flupentixol decanoate (flupenthixol decanoate)

20mg/mL oily solution in 1-mL and 2-mL ampoules; 1-mL and 2-mL syringes; 10-mL vials

# 100 mg/mL oily solution in 0.5-mL and 1-mL ampoules; 5-mL vials 200 mg/mL oily solution in 1-mL ampoules

- · Flupentixol decanoate is a thioxanthene antipsychotic presented as a long-acting depot injection.
- It is used in the treatment of schizophrenia and other psychoses.
- · Doses are expressed in terms of flupentixol decanoate.

#### **Pre-treatment checks**

- · Avoid in patients in comatose states, including alcohol, barbiturate, or opiate poisoning.
- · Not recommended for excitable or agitated patients.
- · Concomitant treatment with other antipsychotics should be avoided.
- Caution in epilepsy, Parkinson disease, liver disease, renal failure, cardiac disease, depression, myasthenia gravis, prostatic hypertrophy, narrow-angle glaucoma, hypothyroidism, hyperthyroidism, phaeochromocytoma, severe respiratory disease or if there are risk factors for stroke.

 FBC

#### Dose

**Test dose:** 20 mg to assess tolerability. Reduce test dose to 5 or 10 mg if patient is elderly. **Maintenance dose:** commence at least one week after test dose, usual dose range 50 mg every 4 weeks up to 300 mg every 2 weeks. Some patients may require up to 400 mg weekly.

#### Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose. The maximum volume to be administered at one site is 2 mL. Volumes >2 mL should be distributed between two injection sites.
- Give by deep IM injection into the upper outer buttock or lateral thigh. Aspirate before injection to avoid inadvertent intravascular injection. Rotate injection sites for subsequent injections.

# Folic acid

#### 15 mg/mL solution in 1-mL ampoules

- Folic acid is a member of the vitamin B group.
- It is used to treat folate-deficient megaloblastic anaemias, usually due to poor nutrition, pregnancy, or antiepileptic drugs.
- It is used to prevent folate deficiency in renal dialysis patients or chronic haemolytic states.

- The parenteral route should only be considered when oral administration is not feasible, or when malabsorption is suspected (although most patients with malabsorption states can absorb adequate amounts of oral folic acid).
- Folic acid injection is an unlicensed product in the UK.

#### **Pre-treatment checks**

Do not give alone for pernicious anaemia and other vitamin  $B_{12}$  deficiency states (may precipitate subacute combined degeneration of the spinal cord).

#### Biochemical and other tests

FBC Red cell folate levels Vitamin B<sub>12</sub> levels

#### Dose

- **Folate-deficient megaloblastic anaemia**: usually 5 mg daily for 4 months (or until term in pregnant women); doses of up to 15 mg daily may be required in malabsorption states. Maintenance dosing of 5 mg every 1–7 days may be required.
- **Prevention of methotrexate-induced side-effects in rheumatic disease** (unlicensed indication): 5 mg once weekly, on a separate day to methotrexate treatment.
- Prophylaxis in chronic haemolytic states/folate deficiency of dialysis: 5 mg every 1–7 days depending on clinical condition.

## Intramuscular injection (unlicensed)

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by deep IM injection.

#### Intravenous injection (unlicensed)

#### Preparation and administration

- · Withdraw the required dose.
- The solution should be clear and yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV injection over 3-5 minutes. Dilute with NaCl 0.9% in the syringe if necessary.

#### Subcutaneous injection (unlicensed)

- 1. Withdraw the required dose.
- 2. Give by SC injection.

| The second state is a second |                                                                                  |  |

# Fondaparinux sodium

# 5 mg/mL solution in pre-filled syringes: 1.5 mg/0.3 mL and 2.5 mg/0.5 mL 12.5 mg/mL solution in pre-filled syringes: 5 mg/0.4 mL, 7.5 mg/0.6 mL and 10 mg/ 0.8 mL

- · Fondaparinux sodium is a synthetic pentasaccharide that acts as a selective inhibitor of Factor Xa.
- It is used in the treatment of STEMI and also in the acute coronary syndromes (ACS): unstable angina and NSTEMI.
- It is used in the treatment of VTE, i.e. pulmonary embolism and deep vein thrombosis.
- It is used for prophylaxis of VTE in surgical and medical patients.
- Routine coagulation tests such as PT and APTT are **not** useful for monitoring.

#### **Pre-treatment checks**

- · Avoid in active bleeding; bacterial endocarditis.
- Do not give if CrCl <20 mL/minute in the UK (in the USA the cut off is CrCl <30 mL/minute).
- · Caution in patients who have developed HIT.
- Use with caution in patients with bodyweight <50 kg as at ↑risk of bleeding (elimination ↓with weight). In the USA it is contraindicated in such patients undergoing hip-fracture, hip-replacement, knee-replacement, or abdominal surgery due to ↑incidence of major bleeding.</li>
- Caution also in any bleeding disorders, active GI ulcer disease; recent intracranial haemorrhage; brain, spinal, or ophthalmic surgery; spinal or epidural anaesthesia (risk of spinal haematoma – avoid if using treatment doses); risk of catheter thrombus during PCI; elderly patients; concomitant use of drugs that *frisk* of bleeding; hepatic impairment, pregnancy and breast feeding.
- Not licensed in the UK for adults <17 years of age.</li>

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure Bodyweight FBC (including platelets) LFTs Renal function: U, Cr, CrCl (or eGFR)

#### Dose

Prophylaxis

**General or orthopaedic surgery with high risk of VTE:** 2.5 mg by SC injection 6 hours after surgery then 2.5 mg once daily until the patient is mobile for at least 5–9 days.

#### 362 | Fondaparinux sodium

Medical patients (high risk of VTE): 2.5 mg by SC injection once daily until the patient is mobile.

#### Treatment

**Treatment of VTE:** give by SC injection once daily based on bodyweight as indicated in Table F1. Treat for at least 5 days and until INR >2.

| Table F1         Treatment doses of fondaparinux for VTE |                 |  |
|----------------------------------------------------------|-----------------|--|
| Bodyweight (kg)                                          | Syringe to use  |  |
| <50                                                      | 5 mg (0.4 mL)   |  |
| 50-100                                                   | 7.5 mg (0.6 mL) |  |
| >100 kg                                                  | 10 mg (0.8 mL)  |  |

**Treatment of ACS:** 2.5 mg by SC injection once daily for up to 8 days or until hospital discharge, whichever comes first.

Unfractionated heparin should be used in patients undergoing PCI and fondaparinux reinstituted as specified in local protocols.

**Treatment of acute STEMI:** 2.5 mg by IV injection or infusion on first day, thereafter 2.5 mg by SC injection once daily for up to 8 days or until hospital discharge, whichever comes first.

Dose in renal impairment: adjusted according to creatinine clearance and indication,

#### **Prophylaxis of VTE:**

- CrCl 20-50 mL/minute: 1.5 mg once daily.
- CrCl <20 mL/minute: do not use.

#### **Treatment of VTE:**

- CrCl 30-50 mL/minute: in patients > 100 kg after initial 10 mg dose, reduce to 7.5 mg daily.
- CrCl <30 mL/minute: do not use.

#### **Treatment of ACS and STEMI:**

- CrCl >20 mL/minute: dose as in normal renal function.
- CrCl <20 mL/minute: do not use.

Dose in hepatic impairment: caution in severe hepatic impairment (*risk* of bleeding).

#### **Subcutaneous injection**

- 1. Select the correct pre-filled syringe. Pre-filled syringes are ready for immediate use; do not expel the air bubble.
- 2. The patient should be seated or lying down.
- Pinch up a skin fold on the abdominal wall between the thumb and forefinger and hold throughout the injection.
- 4. Give by deep SC injection (push the plunger of the syringe the full length of the syringe barrel) into the thick part of the skin fold at right angles to the skin. Do not rub the injection site after administration. Alternate doses between the right and left sides.
- Once the plunger is released, the needle automatically withdraws from the skin and retracts into the security sleeve.

## Intravenous injection (first dose in STEMI only)

#### Preparation and administration

- 1. Select a 2.5-mg pre-filled syringe.
- The solution should be clear and colourless to slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection via an existing IV line.
- 4. Flush with NaCl 0.9% after injection to ensure that the entire dose is administered.
- 5. Once the plunger is released, the needle automatically retracts into the security sleeve.

## Intravenous infusion (alternative route for first dose in STEMI only)

- 1. Select a 2.5-mg pre-filled syringe and add the contents to 50 mL NaCl 0.9%.
- The solution should be clear and colourless to slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 1–2 minutes.
- 4. Once the plunger is released, the needle automatically retracts into the security sleeve.

# **Foscarnet sodium**

#### 24 mg/mL solution in 250-mL and 500-mL infusion bottles

- · Foscarnet sodium is a non-nucleoside analogue with activity against herpes viruses.
- It is used for the treatment of CMV retinitis in AIDS patients and for aciclovir-resistant mucocutaneous HSV infections in immunocompromised patients.

#### **Pre-treatment checks**

- · Caution in patients with neurological or cardiac abnormalities because of electrolyte disturbances.
- Ensure adequate hydration to establish diuresis by giving 500 mL-1 L of NaCl 0.9% or Gluc 5% concurrently with each infusion.

#### Biochemical tests

Electrolytes: serum Ca, K, Mg, PO<sub>4</sub> FBC LFTs Renal function: U, Cr, CrCl (or eGFR)

## Dose

#### **CMV retinitis**:

- Induction: 60 mg/kg every 8 hours for 2-3 weeks.
- Maintenance: 60 mg/kg daily (increased to 90–120 mg/kg if tolerated and/or in progressive retinitis). If retinitis continues to progress on the maintenance dose, then repeat the induction regimen.

**Mucocutaneous herpes simplex infection**: 40 mg/kg every 8 hours for 2–3 weeks or until lesions heal. (No maintenance schedule has been determined for this indication.)

**Dose in renal impairment**: in the UK the manufacturer recommends dosage adjustment according to creatinine clearance expressed as mL/kg/minute. (Calculate the CrCl or eGFR in the normal way and divide the result by the patient's ideal bodyweight.) The dose is then reduced according to the calculated creatinine clearance and the indication, see Table F2.

NB: a different dosing schedule is used in the USA.

| Table F2         Foscarnet dosing in renal impairment |                                            |                                   |                                        |

#### Intermittent intravenous infusion

- See Special handling below.
- Foscarnet sodium is incompatible with Hartmann's, Ringer's and other solutions or preparations containing calcium.
- Foscarnet sodium must not be given by rapid IV infusion or injection.
- The 24 mg/mL solution may be given without dilution via a central vein.
- If a peripheral vein is used, the solution must be diluted to give a solution containing 12 mg/ mL before administration.

#### 366 | Foscarnet sodium

- Calculate the required total dose. To minimise the risk of overdosage, any drug in excess of the patient's calculated dose should be removed from the infusion bottle and discarded prior to administration.
- If the infusion is to be given via a peripheral vein, dilute the dose with an equal quantity of NaCl 0.9% before administration. Alternatively, some centres piggyback 1L NaCl 0.9% to run concurrently with the foscarnet dose.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion using a controlled infusion device. Give up to 60 mg/kg over a minimum of 60 minutes; for higher doses the infusion time should be increased proportionately.

Moderate-risk product: Risk-reduction strategies are recommended.

## Bibliography

SPC Foscavir (accessed 18 March 2009).

# Fosphenytoin sodium

#### 75 mg/mL solution in 10-mL vials $\equiv$ 50 mg/mL phenytoin sodium $\equiv$ 50 mg PE/mL

- Fosphenytoin is a pro-drug of phenytoin. Phenytoin sodium is a hydantoin antiepileptic agent believed to act by preventing the spread of seizure activity, rather than raising seizure threshold.
- Fosphenytoin sodium is used in the management of status epilepticus, as a substitute for phenytoin when parenteral therapy is indicated, and for prophylactic control of seizures in neurosurgery or following serious head injury.

Fosphenytoin sodium doses are expressed in terms of phenytoin sodium equivalents (PE): All labelling and all prescriptions must specify doses as phenytoin sodium equivalents (PE) to avoid confusion:

- Fosphenytoin sodium  $1.5 \text{ mg} \equiv 1 \text{ mg PE}$  (phenytoin sodium equivalent).
- Fosphenytoin 1 mmol is metabolised to 1 mmol phenytoin.

#### UK CSM advice (May 2000)

IV infusion of fosphenytoin has been associated with severe cardiovascular reactions including asystole, ventricular fibrillation, and cardiac arrest.  $\downarrow$ BP,  $\downarrow$ pulse and heart block have also been reported. The CSM advises:

- Monitor heart rate, BP and respiratory function for duration of infusion.
- Observe the patient for at least 30 minutes after the end of the infusion.
- If  $\downarrow$ BP occurs, reduce the infusion rate or discontinue administration.
- A lower loading dose and/or infusion rate may be required in elderly patients and in those with renal or hepatic impairment.

#### **Pre-treatment checks**

- Ensure that resuscitation facilities are available.
- Avoid in acute porphyria.
- Caution in JBP, Jpulse, heart failure, previous myocardial infarction, sinoatrial block, second- and third-degree heart block and Stokes–Adams syndrome.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Blood pressure | FBC                    |
|----------------|------------------------|
| Bodyweight     | LFTs including albumin |
| ECG            | Pregnancy test         |

#### Dose

For existing epilepsy patients switched from oral phenytoin maintenance to parenteral fosphenytoin:

- Capsules (containing phenytoin sodium)  $100 \text{ mg} \equiv 100 \text{ mg}$  PE fosphenytoin IV.
- Suspension (containing phenytoin base)  $90 \text{ mg} \cong 100 \text{ mg}$  PE fosphenytoin IV.

Phenytoin exhibits non-linear pharmacokinetics (minor dose changes can have a significant effect on phenytoin levels) – always monitor levels closely when the route is changed.

**Status epilepticus:** 20 mg (PE)/kg by IV infusion then 4–5 mg (PE)/kg daily in 1–2 divided doses by IV infusion or IM injection. Adjust dosage according to phenytoin levels and change to oral phenytoin as soon as possible.

**Seizure prophylaxis or treatment during neurosurgery or following head injury**: 10–15 mg (PE)/kg by IV infusion or IM injection, then 4–5 mg (PE)/kg daily in 1–2 divided doses by IV infusion or IM injection. Adjust dosage according to phenytoin levels and change to oral phenytoin as soon as possible.

Temporary replacement of oral phenytoin: see dosage statement above.

**Dose in elderly patients and in renal and hepatic impairment:** the manufacturer recommends a 10–25% reduction in dose or infusion rate be considered (except initial dose for status epilepticus). No reference is made to the degree of renal or hepatic impairment requiring such reductions; be guided by clinical response and plasma concentrations.

#### Intravenous infusion

#### Preparation and administration

- 1. Withdraw the required dose and add to a suitable volume of NaCl 0.9% or Gluc 5% to give a solution containing 1.5–25 mg (PE)/mL. Use 25 mg (PE)/mL for status epilepticus.
- 2. The solution should be clear and colourless to faintly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV infusion using a rate controlled infusion device at a maximum rate of 150 mg (PE)/ minute:
  - Rate for status epilepticus loading dose: 100-150 mg (PE)/minute.
  - Rate for all other indications and further doses 50-100 mg (PE)/minute.

#### Intramuscular injection

This route is not suitable for status epilepticus.

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by deep IM injection.

| Action in case of overdose                | Symptoms: ↑ or ↓pulse, asystole, respiratory or circulatory depression,<br>cardiac arrest, syncope, ↓Ca, metabolic acidosis and death.<br>Antidote: No known antidote but haemodialysis may be used, as about<br>10% of phenytoin is not protein bound.<br>Stop administration and give supportive therapy as appropriate. Phenytoin<br>plasma levels should be checked as soon as possible.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |  |
| Counselling                               | Women who have been relying on the combined contraceptive pill should be advised to take additional precautions.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |  |

#### 372 | Fosphenytoin sodium | Furosemide

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Pro-Epanutin concentrate for infusion/solution for injection (accessed 10 October 2008).

# Furosemide (frusemide)

#### 10 mg/mL solution in 2-mL, 5-mL and 25-mL ampoules or vials

- · Furosemide is a loop diuretic with a rapid action.
- It is indicated for use when prompt and effective diuresis is required.
- The IV formulation is appropriate for use in emergencies or when the oral route is unavailable or ineffective: indications include cardiac, pulmonary, hepatic and renal oedema.

#### **Pre-treatment checks**

- Do not use in hypovolaemia, dehydration, severe ↓K, severe ↓Na; comatose or precomatose states associated with liver cirrhosis; renal failure due to nephrotoxic or hepatotoxic drugs, anuria.
- Caution in 

   BP; prostatic enlargement; impaired micturition; gout; diabetes; hepatorenal syndrome; hepatic impairment; renal impairment.
- Fluid balance and electrolytes should be carefully controlled and, in particular, in patients with shock, measures should be taken to correct BP and circulating blood volume before commencing treatment.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| Blood glucose                 | LFTs                                  |
|-------------------------------|---------------------------------------|
| Blood pressure                | Renal function: U, Cr, CrCl (or eGFR) |
| Electrolytes: serum Na, K, Mg |                                       |

#### Dose

**Standard initial dose**: 20–50 mg. If larger doses are required, they should be given increasing by 20-mg increments and not given more often than every 2 hours.

**Oliguria in acute or chronic renal failure** (GFR <20 mL/minute but >5 mL/minute): the following doses have been used:

- 1. Initially 250 mg infused over 1 hour.
- 2. If urine output is insufficient within the next hour, this dose may be followed by 500 mg infused over about 2 hours.

- 3. If a satisfactory urine output has still not been achieved within 1 hour of the end of the second infusion, then a third dose of 1 g may be infused over about 4 hours.
- 4. If the response is satisfactory, the effective dose (up to 1 g) may then be repeated every 24 hours.

The recommended maximum daily dose is 1500 mg.

## Intravenous infusion (preferred route for doses >50 mg)

#### Preparation and administration

- 1. Withdraw the required dose. Depending on hydration status, either give undiluted using a syringe pump or add to a convenient volume of NaCl 0.9%.
- The solution should be clear and colourless or almost colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion at a rate no greater than 4 mg/minute, i.e. a dose of 100 mg must be infused over at least 25 minutes. In severe renal impairment the rate may be reduced to 2.5 mg/minute to reduce the likelihood of ototoxicity.

## Intravenous injection (may be suitable for doses <50 mg)

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless or almost colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 3-5 minutes. Note: rapid injection may cause tinnitus and deafness.

#### Intramuscular injection

#### Preparation and administration

Restrict to exceptional cases (and only for doses  $\leq$ 50 mg) where neither the oral nor IV routes are available. IM use is not suitable for the treatment of acute conditions such as pulmonary oedema.

- 1. Withdraw the required dose.
- 2. Give by IM injection.

# Ganciclovir

#### 500-mg dry powder vials

- Ganciclovir sodium is a synthetic nucleoside analogue of guanine.
- It is used for the treatment and suppression of life-threatening or sight-threatening CMV infections in immunocompromised patients.
- Doses are expressed in terms of the base: Ganciclovir 500 mg ≅ 545 mg ganciclovir sodium.

#### **Pre-treatment checks**

- Do not give if there is known hypersensitivity to ganciclovir, valganciclovir, aciclovir or valaciclovir.
- Ensure that the patient is adequately hydrated (excretion depends on adequate renal function).

#### Biochemical and other tests

Bodyweight FBC (do not initiate if the absolute neutrophil count is <500 cells/mm<sup>3</sup> ( $0.5 \times 10^9$ /L), or platelet count <25 000/mm<sup>3</sup> ( $25 \times 10^9$ /L), or haemoglobin <8 g/dL) Ophthalmological examination Renal function: U, Cr, CrCl (or eGFR)

#### Dose

Ganciclovir sodium must not be given by IV injection as excessive plasma levels result in †toxicity. It must not be given by IM or SC injection because the high pH causes tissue irritation.

#### CMV infection

Induction: 5 mg/kg every 12 hours for 14-21 days.

**Maintenance**: 6 mg/kg once daily 5 days per week, or 5 mg/kg once daily 7 days per week (used for immunocompromised patients at risk of relapse of CMV retinitis). If retinitis continues to progress on the maintenance dose then repeat the induction regimen.

#### Prevention of CMV disease

**Induction**: 5 mg/kg infused every 12 hours for 7–14 days. **Maintenance**: 6 mg/kg once daily 5 days per week, or 5 mg/kg once daily 7 days per week.

Dose in renal impairment: adjusted according to creatinine clearance.

- CrCl >70 mL/minute: dose as in normal renal function.
- CrCl 50–69 mL/minute: 2.5 mg/kg every 12 hours (induction); 2.5 mg/kg every 24 hours (maintenance).
- CrCl 25–49 mL/minute: 2.5 mg/kg every 24 hours (induction); 1.25 mg/kg every 24 hours (maintenance).
- CrCl 10-24 mL/minute: 1.25 mg/kg every 24 hours (induction); 0.625 mg/kg every 24 hours (maintenance).
- CrCl <10 mL/minute: 1.25 mg/kg shortly after haemodialysis (induction); 0.625 mg/kg shortly after haemodialysis (maintenance). NB: In the USA a maximum of 3 doses per week is recommended.

# Intermittent intravenous infusion

Give via a large peripheral or central vein. See Special handling below.

- 1. Add 10 mL WFI to the vial and shake to dissolve. This gives a concentration of 50 mg/mL.
- 2. Withdraw the required dose and transfer to 50–250 mL of compatible infusion fluid (usually 100 mL NaCl 0.9% is used). The final concentration must not exceed 10 mg/mL.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion at a constant rate over 60 minutes via a large peripheral or central vein (†blood flow is essential to ensure rapid dilution and distribution). A controlled-infusion device is recommended for more concentrated solutions.

of No known antidote but rehydration and haemodialysis may be effective.
 Stop administration and give supportive therapy as appropriate.

Potentially teratogenic and may cause temporary or permanent inhibition of spermatogenesis. Women of child-bearing potential must use effective contraception during treatment, and men must use barrier contraception during and for at least 90 days after treatment (unless certain that the female partner is not at risk of pregnancy).

Risk rating: AMBER

overdose

Counselling

Score = 5

Moderate-risk product: Risk-reduction strategies are recommended.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

### **Bibliography**

SPC Cymevene powder for infusion (accessed 11 March 2008).

# Gelatin

# 3%, 3.5% and 4% solutions (with varying amounts of electrolytes) in 500-mL or 1000-mL infusion containers

- Gelatin preparations are colloidal plasma substitutes. They contain large molecules that do not readily leave the intravascular space where they exert osmotic pressure to maintain circulatory volume. Compared with crystalloids, smaller volumes are required to produce the same expansion of blood volume.
- They are used in the initial short-term management of hypovolaemic shock caused by conditions such as burns, septicaemia, haemorrhage, acute trauma or surgery. Blood products should be given as soon as available if appropriate.
- Use of gelatin-containing infusion fluids may ↑risk of bleeding owing to dilution of clotting factors.
- Table G1 shows the gelatin and electrolyte content of the commercially available products.

"As either succinylated gelatin (Gelofusine, Geloplasma, Isoplex, Volplex) or polygeline (Haemaccel)

#### **Pre-treatment checks**

- · Preparations containing lactate are contraindicated in patients with liver disease.
- Extreme caution should be used in those patients likely to develop circulatory overload such as in congestive cardiac failure, renal failure and pulmonary oedema.
- · Caution should also be used in those patients at risk of liver disease and bleeding disorders.

#### 380 | Gelatin

- Patients with known allergic disorders (e.g. asthma) may be more likely to suffer an allergic reaction.
- · Dehydration should be corrected prior to or during treatment.

Biochemical and other tests (not all are necessary in an emergency situation)

Electrolytes: serum Na, K FBC Urinary output

#### Dose

**Hypovolaemic shock:** initial volumes of 500–1000 mL may be required. The volume given and rate of infusion will depend on the condition of the patient. In severe acute blood loss may be given rapidly (500 mL in 5–10 minutes).

#### Intravenous infusion

Preparation and administration

Preparations containing Ca are not compatible with citrated blood.

- 1. If the infusion is to be given rapidly, warm container to no more than 37°C if possible.
- 2. The infusion is pre-prepared for use. It should be clear and pale yellow or straw coloured. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion at the required rate; pressure may be applied to the container to hasten administration.
- 4. Discard any unused portion. Do not reconnect partially used infusion containers.

# Gentamicin

#### 40 mg/mL solution in 1-mL or 2-mL ampoules or vials; 10 mg/mL solution in 2-mL vials

- Gentamicin sulfate is classed as an aminoglycoside antibiotic and is a mixture of antibiotic substances produced by the growth of *Micromonospora purpurea*.
- It is active against many Gram-negative aerobic bacteria and against some species of staphylococci.
- It has a narrow therapeutic range, with its two most serious adverse reactions ototoxicity and nephrotoxicity – being dose related.
- Dose is calculated on the basis of renal function (as it is almost completely renally excreted) and body weight. However, gentamicin is not lipophilic, so dose should be based on ideal bodyweight (IBW) rather than actual bodyweight (ABW). Some authorities recommend using a 'dosing weight' calculated by adding IBW to 40% of the difference between ABW and IBW. Whichever method is employed it is important to check these criteria to avoid overdosing, e.g. in short, obese individuals with impaired renal function.
- Traditionally gentamicin has been given every 8 or 12 hours, but many hospitals have now adopted once-daily dosing regimens, with diverse methods of dosing, monitoring and subsequent dose adjustment. Seek out your local policy.
- · Doses are expressed in terms of gentamicin base.

#### **Pre-treatment checks**

- · Do not give in myasthenia gravis.
- Ensure good hydration status (dehydration ↑risk of toxicity).

#### Biochemical and other tests

Baseline check of auditory and vestibular function Bodyweight (and possibly height if patient over-weight) FBC

Renal function: U, Cr, CrCl (or eGFR)

#### Dose

To avoid excessive dosing, doses for all regimens should be calculated on the basis of ideal bodyweight (IBW) in obese patients.

#### Multiple daily dosing regimen

**Standard dose**: give by IV injection or infusion every 6–8 hours to provide a total daily dose of 3–5 mg/kg.

Endocarditis: 1 mg/kg every 8 hours (in combination with other antibacterials).

Dose in renal impairment: adjusted according to creatinine clearance:1

- CrCl >70 mL/minute: 80 mg\* every 8 hours and monitor levels.
- CrCl >30-70 mL/minute: 80 mg\* every 12 hours and monitor levels.
- CrCl 10-30 mL/minute: 80 mg\* every 24 hours and monitor levels.
- CrCl  ${<}10\,mL/minute{:}~80\,mg^{\star}$  every 48 hours and monitor levels.

\*If bodyweight <60 kg, use 60 mg.

#### Once-daily dosing regimen

**Standard dose**: 5–7 mg/kg by IV infusion every 24 hours (or according to local guidelines). It is suggested that the dose be rounded to the nearest 20 mg to facilitate measurement. **Dose in renal impairment**: adjusted according to creatinine clearance:<sup>2</sup>

- CrCl 30–70 mL/minute: 3–5 mg/kg IBW every 24 hours and monitor levels.
- CrCl 10-30 mL/minute: 2-3 mg/kg IBW every 24 hours and monitor levels.
- CrCl 5-10 mL/minute: 2 mg/kg IBW every 48-72 hours and monitor levels.

#### Intermittent intravenous infusion

Preparation and administration

If used in combination with a penicillin or cephalosporin, preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Withdraw the required dose and add to a suitable volume of compatible infusion fluid (usually 100 mL NaCl 0.9%).
- The solution should be clear and colourless to very pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 30-60 minutes.

#### Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- Give by IM injection into a large muscle such as the gluteus or the lateral aspect of the thigh. Volumes >4 mL should be distributed between two or more injection sites.

#### Intravenous injection

#### Preparation and administration

Direct IV injection should not be used for once-daily dosing regimen:  $\uparrow$ risk of neuromuscular blockade.

If used in combination with a penicillin or cephalosporin, preferably administer at a different site. If this is not possible then flush the line thoroughly with a compatible solution between drugs.

- 1. Withdraw the required dose.
- The solution should be clear and colourless to pale yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over a minimum of 3-5 minutes.

# **Glatiramer acetate**

#### 20 mg/mL solution in 1-mL pre-filled syringe

- Glatiramer is a peptide (a random polymer of L-alanine, L-glutamic acid, L-lysine, and L-tyrosine) that has some structural resemblance to myelin basic protein.
- It is used to ↓ frequency of relapses in the management of relapsing-remitting multiple sclerosis.
- Doses are expressed as glatiramer acetate: Glatiramer acetate 20 mg ≈ 18 mg glatiramer base.

#### **Pre-treatment checks**

- Do not give if hypersensitive to mannitol or glatiramer.
- · Caution in patients with pre-existing cardiac disorders.

#### Biochemical tests

Renal function: U, Cr

#### Dose

Standard dose: 20 mg daily by SC injection.

#### **Subcutaneous injection**

#### Preparation and administration

- 1. Remove the syringe from the refrigerator and allow to warm to room temperature for 20 minutes before use.
- Give by SC injection into the abdomen, arm, hip or thigh. Injection-site rotation should be planned for subsequent injections so that any one area is not injected more than once a week.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

### Bibliography

SPC Copaxone 20 mg/mL, solution for injection, pre-filled syringe (accessed 23 February 2010).

# Glucagon

#### 1-mg dry powder vials with pre-filled syringes containing 1.1 mL WFI

- Glucagon is an endogenous polypeptide hormone produced by the alpha cells of the pancreatic islets of Langerhans. Its release mobilises glucose by activating hepatic glycogenolysis.
- It is used in the treatment of severe hypoglycaemia when the patient cannot take glucose by mouth and the use of IV glucose is not feasible.
- Glucagon may be used to relax specific areas of the GI tract for diagnostic purposes because it has a relaxant effect on smooth muscle.
- It is also used (unlicensed) in beta-blocker overdose to bypass blocked beta-receptors in severe \u00c4BP, heart failure or cardiogenic shock because it has chronotropic and inotropic effects that are independent of a response to catecholamine
- Although structurally identical to endogenous human glucagon, commercially available glucagon is prepared using recombinant DNA technology.
- Glucagon  $1 \text{ mg} \equiv 1$  unit glucagon.

#### **Pre-treatment checks**

- Avoid use in phaeochromocytoma.
- · Use with caution in glucagonoma and insulinoma.
- Use with caution if using for diagnostic purposes in patients with diabetes mellitus or in elderly
  patients with known cardiac disease.
- The hyperglycaemic action of glucagon is dependent on the presence of liver glycogen. It is unlikely to be effective in starvation, adrenal insufficiency, chronic hypoglycaemia or alcoholinduced hypoglycaemia.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood glucose Blood pressure and pulse Electrolytes: serum K, Ca

#### Dose

**Hypoglycaemia:** 1 mg by SC or IM injection. The patient will normally respond within 10 minutes. When the patient has responded to the treatment, give oral carbohydrate to restore the liver glycogen and prevent further hypoglycaemia. If the patient does not respond within 10 minutes, give IV glucose.

**Diagnostic aid in GI examinations to inhibit motility:** usual dose for relaxation of the stomach, duodenal bulb, duodenum and small bowel is 0.2–0.5 mg by IV injection or 1 mg by IM injection; the usual dose to relax the colon is 0.5–0.75 mg by IV injection or 1–2 mg by IM injection.

- Onset of action after IV injection occurs within 1 minute and the duration of effect is 5–20 minutes.
- Onset of action after IM injection occurs after 5–15 minutes and lasts approximately 10–40 minutes.

#### Beta-blocker overdose (unlicensed):

It is essential to consult a poisons information service, e.g. Toxbase at www.toxbase.org (password or registration required) for full details of the management of beta-blocker toxicity.

5-10 mg by slow IV injection over 10 minutes (to reduce the likelihood of vomiting); followed by an infusion of 1-5 mg/hour (50 micrograms/kg/hour) titrated to clinical response.<sup>1</sup>

#### Intramuscular injection

#### Preparation and administration

- 1. Inject the WFI provided (1.1 mL) into the vial. Shake gently until completely dissolved to give a solution containing 1 mg/mL (1 unit/mL).
- 2. The solution should be clear and colourless. If the solution shows signs of fibril formation (*\viscosity*) or insoluble matter it should be discarded.
- 3. Withdraw the required dose
- 4. Give by IM injection.

#### **Subcutaneous injection**

#### Preparation and administration

- 1. Inject the WFI provided (1.1 mL) into the vial. Shake gently until completely dissolved to give a solution containing 1 mg/mL (1 unit/mL).
- 2. The solution should be clear and colourless. If the solution shows signs of fibril formation (*\viscosity*) or insoluble matter it should be discarded.
- 3. Withdraw the required dose.
- 4. Give by SC injection.

#### Intravenous injection

#### Preparation and administration

- 1. Inject the WFI provided (1.1 mL) into the vial. Shake gently until completely dissolved to give a solution containing 1 mg/mL (1 unit/mL).
- 2. Withdraw the required dose.
- 3. The solution should be clear and colourless. If the solution shows signs of fibril formation (*\viscosity*) or insoluble matter it should be discarded.
- Give by IV injection. Give doses >1 mg slowly over 10 minutes to ↓likelihood of nausea and vomiting.

#### Intravenous infusion (unlicensed)

NB: The solvent provided no longer contains preservative and is safe to use for the reconstitution of large doses.

#### Preparation and administration

- 1. Inject the WFI provided (1.1 mL) into the vial. Shake gently until completely dissolved to give a solution containing 1 mg/mL (1 unit/mL).
- 2. Withdraw the required dose and add to a suitable volume of Gluc 5%.
- 3. The solution should be clear and colourless. If the solution shows signs of fibril formation (*\viscosity*) or insoluble matter it should be discarded.
- 4. Give by IV infusion via a volumetric infusion device. Adjust rate to clinical response.

# Glucose (dextrose monohydrate)

# 5%, 10%, 20%, 25% and 50% solution in ampoules and infusion bags of various volumes 50% solution in 50-mL pre-filled syringes

- Glucose is a monosaccharide which, when dissolved in water, is used as an electrolyte-free crystalloid intravenous fluid that disperses through the intra- and extracellular fluid as water. It is sometimes referred to as dextrose (see also Appendix 1) but should always be prescribed as glucose in the UK.
- It is given by IV infusion to treat fluid depletion and maintain hydration. However, sole use of
  electrolyte-free glucose-containing infusion fluids causes electrolyte depletion. Glucose is also
  used as an energy source in combination with other nutrients in parenteral nutrition.
- Glucose is given by IV injection or infusion in the treatment of hypoglycaemia; it is also given by IV infusion to maintain blood glucose levels in patients receiving insulin infusions.
- It is given alongside insulin in the treatment of severe ↑K, so that hypoglycaemia is avoided (see the Insulins monograph).
- Gluc 5% may be used as a vehicle or diluent for the administration of compatible parenteral drugs. It may also be given (unlicensed) by SC infusion (hypodermoclysis).
- The concentration of glucose solutions for IV use in the UK (and in this monograph) are expressed in terms of the percentage w/v of anhydrous glucose. In the USA and some other countries, concentrations are expressed in terms of the percentage w/v of glucose monohydrate.

#### **Pre-treatment checks**

- Hypertonic glucose solutions are contraindicated in patients with anuria, intraspinal or intracranial haemorrhage, ischaemic stroke and hyperglycaemic coma and in patients with delirium tremens.
- Caution in patients with diabetes mellitus and impaired glucose tolerance, severe under-nutrition, thiamine deficiency, 1PO<sub>4</sub>, haemodilution, sepsis, trauma, shock, metabolic acidosis or severe dehydration.

#### 392 | Glucose

 Gluc 5% solutions are used mainly to treat fluid depletion but should be given alone only when there is no significant loss of electrolytes (prolonged administration of glucose solutions without electrolytes can lead to 1Na and other electrolyte disturbances).

Biochemical and other tests (not all are necessary in an emergency situation)

Blood glucose Electrolytes: serum Na Fluid balance

#### Dose

Glucose 5% is approximately isotonic with plasma and may be given via peripheral vein. Solutions >5% are hypertonic (see osmolarity below) and where possible should be given via a central line, although some sources suggest that 10% solutions may be given via a large peripheral vein for short periods provided the infusion site is changed at least daily. In emergency situations it may be necessary to administer hypertonic solutions peripherally.

**Treatment or prevention of fluid depletion:** dose is dependent upon the age, weight, biochemistry and clinical condition of the patient. Normal fluid requirements are generally about 40 mL/kg/ 24 hours. Glucose solutions are usually used in combination with electrolyte-containing solutions so that electrolyte depletion is avoided. The use of colloid solutions should be considered where plasma expansion is required due to ↑losses.

**Treatment of severe hypoglycaemia:** 50 mL Gluc 20% (preferred)<sup>1</sup> or 20–50 mL Gluc 50% by slow IV injection into a large vein; the dose may be repeated as necessary according to the patient's response. Gluc 50% is available in a pre-filled syringe but is very viscous, making it difficult to administer.

Lower concentrations are equally effective, and carry less risk of venous irritation, but larger volumes are required, e.g. up to 250 mL Gluc 5%, or 100 mL Gluc 10%, titrated to patient response.

- Once the patient has regained consciousness oral carbohydrate is given to prevent relapse.
- Hypoglycaemia caused by insulin or oral hypoglycaemic agents requires close monitoring as the duration of action of these agents may be prolonged; further glucose administration may be required.

#### Intravenous infusion

#### Preparation and administration

- 1. The infusion is pre-prepared for use. It should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV infusion at the required rate; give hypertonic solutions via a central venous catheter (see information above).
- 3. Discard any unused portion. Do not reconnect partially used infusion containers.

#### Intravenous injection (emergency treatment of hypoglycaemia)

#### Preparation and administration

- 1. Withdraw the required dose from an IV infusion bag or (if using 50% glucose) assemble a pre-filled syringe in accordance with the manufacturer's instructions.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV injection over 1-2 minutes.
- 4. Give oral carbohydrate once the patient has regained consciousness.

monograph. These may not all be applicable in some clinical situations.

# Glyceryl trinitrate (GTN, nitroglycerin, nitroglycerol)

## 1 mg/mL solution in 5-mL and 10-mL ampoules and 25-mL and 50-mL vials

### 5 mg/mL solution in 5 -mL and 10 -mL ampoules; 10 mg/mL solution in 10 -mL ampoules

- Glyceryl trinitrate relaxes smooth vascular muscle, reducing cardiac filling pressure and volume (pre-load), and lowering myocardial oxygen demand.
- It is used in unresponsive congestive heart failure, acute left-sided heart failure, acute MI, refractory unstable angina pectoris and coronary insufficiency including Prinzmetal's angina.
- It is also used in induction of controlled hypotension for surgery and in the control of hypertensive episodes and/or myocardial ischaemia during and after cardiac surgery.

#### **Pre-treatment checks**

- Do not give in hypersensitivity to nitrates, severe anaemia, *î*intracranial pressure due to head trauma or cerebral haemorrhage, uncorrected hypovolaemia and hypotensive shock, arterial hypoxaemia and angina caused by hypertrophic obstructive cardiomyopathy, constrictive pericarditis, pericardial tamponade or toxic pulmonary oedema.
- · Caution in severe renal/hepatic impairment, hypothyroidism, malnutrition, or hypothermia.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Electrolytes: serum Na, K Renal function: U, Cr, CrCl (or eGFR)

#### Dose

Initiate at the following doses then titrate against individual clinical response (usual range 10–200 micrograms/minute):

Congestive heart failure: initially 10 micrograms/minute.

**Refractory unstable angina pectoris**: initially 10–15 micrograms/minute increasing in increments of 5–10 micrograms approximately every 30 minutes either until angina is relieved, headache limits further dose increase or mean arterial pressure falls by >20 mmHg.

**Surgery**: initially 5–25 micrograms/minute (or according to local protocol), titrating gradually to desired systolic arterial pressure.

#### Continuous intravenous infusion via syringe pump

#### Preparation and administration

Avoid use of PVC infusion containers, administration sets and in-line filters if possible. Significant losses (>40%) occur by adsorption or absorption, requiring higher infusion rates to be employed. This effect is not significant with rigid plastics, e.g. polyethylene or polypropylene syringes and administration sets. Administration using a syringe pump is the most effective way of giving glyceryl trinitrate by infusion.

- Withdraw 50 mL of the 1 mg/mL strength into a syringe suitable for use with a syringe pump. Alternatively, withdraw 10 mL of the 5 mg/mL strength and make up to 50 mL with NaCl 0.9%. Cap the syringe and mix well to give a solution containing 1 mg/mL.
- The solution should be clear and colourless to slightly yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV infusion using a syringe pump. For most indications the starting infusion rate is 10
  micrograms/minute (0.6 mL/hour). Adjust the dose to clinical response as indicated above.

# Glycopyrronium bromide (glycopyrrolate)

#### 200 micrograms/mL solution in 1-mL and 3-mL ampoules

- Glycopyrronium bromide is an antimuscarinic agent with largely peripheral actions. It has antispasmodic actions on smooth muscle and reduces salivary and bronchial secretions. It depresses the vagus and thereby increases the heart rate.
- It is used preoperatively to reduce secretions; to treat symptomatic sinus bradycardia induced by drugs; to prevent muscarinic effects on the heart (e.g. \pulse) during surgery; and in combination with neostigmine during reversal of effect of non-depolarising muscle relaxants.
- Glycopyrronium bromide may also be given (unlicensed) by SC infusion in palliative care to reduce excessive respiratory secretions and relieve bowel colic.

#### 398 | Glycopyrronium bromide

#### **Pre-treatment checks**

- Use with caution in patients with coronary artery disease, congestive heart failure, cardiac arrhythmias, myasthenia gravis, hypertension and thyrotoxicosis.
- · Care should also be taken in pyrexial patients due to the inhibition of sweating.

#### Biochemical and other tests

Blood pressure Bodyweight

#### Dose

**Premedication:** 200–400 micrograms *or* 4–5 micrograms/kg (maximum 400 micrograms) by IM or IV injection.

**Intraoperative use:** 200–400 micrograms *or* 4–5 micrograms/kg (maximum 400 micrograms) by IV injection, repeated if necessary.

**Control of muscarinic side-effects of neostigmine in reversal of non-depolarising neuromuscular block:** 200 micrograms per 1 mg of neostigmine *or* 10–15 micrograms/kg per 50 micrograms of neostigmine by IV injection. The two drugs can be mixed in the same syringe which provides greater cardiovascular stability.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by slow IV injection over 1 minute.

#### Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

# Goserelin

#### 3.6-mg or 10.8-mg implant with sterile applicator

- · Goserelin acetate is a synthetic analogue of gonadorelin (gonadotrophin-releasing hormone).
- It is used for the suppression of testosterone in the treatment of prostate cancer, and for the treatment breast cancer in pre- and perimenopausal women.
- It is used in the treatment of endometriosis and uterine fibroids. It may also be given before surgery for
  endometrial ablation and as an adjunct to ovulation induction with gonadotrophins for infertility.
- · Doses are expressed in terms of goserelin base.

#### **Pre-treatment checks**

Caution in diabetes and osteoporosis (or those at risk, i.e. chronic alcohol and/or tobacco use, strong family history of osteoporosis, or chronic use of drugs that can reduce bone mass such as anticonvulsants or corticosteroids).

#### Biochemical and other tests

Blood pressure Bone mineral density: consider if treatment is to be prolonged Pregnancy test (for assisted reproduction) Testosterone level (in prostate cancer)

#### Dose

**Prostate cancer:** 3.6 mg by SC injection every 28 days or 10.8 mg every 12 weeks. An antiandrogen agent may be given for 3 days before until 3 weeks after commencement to ↓risk of disease flare, e.g. cyproterone acetate 100 mg three times daily.

Breast cancer: 3.6 mg by SC injection every 28 days.

**Endometriosis:** 3.6 mg by SC injection every 28 days for a maximum 6 months (do not repeat). Supplementary combined HRT may reduce bone mineral density loss and vasomotor symptoms.

**Endometrial thinning before intrauterine surgery**: 3.6 mg (may be repeated after 28 days if the uterus is large or to allow flexible surgical timing).

**Before surgery in women who have anaemia due to uterine fibroids**: 3.6 mg every 28 days (with supplementary iron) for a maximum duration 3 months.

**Assisted reproduction:** 3.6 mg is administered to down-regulate the pituitary gland. Serum estradiol levels should decline to levels similar to those in the early follicular phase in 7–21 days. Gonadotrophin is then administered following the protocol of the individual clinic.

#### **Subcutaneous injection**

Preparation and administration

- 1. A local anaesthetic may be given prior to implantation.
- 2. Give by SC injection into the anterior abdominal wall.

| Technical information |                                                               |  |

# Granisetron

#### 1 mg/mL solution in 1-mL and 3-mL ampoules

- · Granisetron hydrochloride is a 5-HT<sub>3</sub> antagonist with antiemetic activity.
- It is used to treat nausea and vomiting associated with cytotoxic chemotherapy and radiotherapy, and also to prevent and treat PONV.
- Co-administration of dexamethasone or methylprednisolone may ↑efficacy of granisetron.
- Doses are expressed in terms of the base: Granisetron 1 mg ≡1.12 mg granisetron hydrochloride.

#### **Pre-treatment checks**

Patients with signs of subacute intestinal obstruction should be monitored following administration as granisetron may llower bowel mobility.

#### Dose

**Prevention of nausea and vomiting induced by cytotoxic chemotherapy**: 1–3 mg by IV injection or infusion not less than 30 minutes prior to start of chemotherapy. Most patients only require a single dose but up to two additional doses of 3 mg may be given in a 24-hour period (not less than 10 minutes apart).

**Treatment of nausea and vomiting induced by cytotoxic chemotherapy:** 3 mg by IV injection or infusion. Up to two additional doses of 3 mg may be administered in a 24-hour period. These additional doses must be given at least 10 minutes apart.

Prevention of PONV: 1 mg by IV injection before induction of anaesthesia.

Treatment of PONV: 1 mg by IV injection; maximum 2 mg in 24 hours.

#### Intravenous injection

#### Preparation and administration

- 1. Withdraw the required dose and dilute each 1 mg (1 mL) to 5 mL with NaCl 0.9% in the syringe.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over a minimum of 30 seconds.

#### Intravenous infusion

#### Preparation and administration

- 1. Withdraw the required dose and add to 50 mL of compatible infusion fluid (usually NaCl 0.9%).
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over 5 minutes.

### Bibliography

SPCs Kytril 1 mg and 3 mg (accessed 5 September 2009).

# **Guanethidine monosulfate**

#### 10 mg/mL solution in 1-mL ampoules

- Guanethidine monosulfate is a peripheral sympathetic blocking drug that is thought to lower BP by depleting and inhibiting reformation of noradrenaline at nerve endings.
- It has been used in hypertensive crises, but its use has largely been superseded. It is now restricted
  to situations where alternative treatments are not effective.

#### **Pre-treatment checks**

- Do not use in patients with phaeochromocytoma or on MAOI drugs, in cardiac failure not associated with *fBP*, and where renal function is compromised (CrCl <41 mL/minute).</li>
- Treatment with guanethidine should be stopped 2 or 3 days prior to surgery.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Renal function: U, Cr, CrCl (or eGFR)

#### Dose

**Standard dose**: 10–20 mg by IM injection; repeat after 3 hours if necessary (longer in renal impairment to avoid accumulation).

**Dose in renal impairment:** extend dosing interval in moderate renal impairment; avoid use in severe renal impairment.

#### Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Ismelin ampoules 10 mg/mL (accessed 6 September 2009).

# Haloperidol

#### 5 mg/mL solution in 1-mL ampoules

#### This preparation must not be confused with the depot preparation.

- Haloperidol is a butyrophenone antipsychotic with a wide range of actions. It is a dopamine inhibitor and has antiemetic activity.
- It is used parenterally in the short-term management of acutely disturbed patients suffering from schizophrenia or other psychoses, mania, hypomania and other mental or behavioural problems. Oral treatment should succeed parenteral administration as soon as is practicable.
- Haloperidol may also be given (unlicensed) by SC infusion in palliative care to treat nausea and vomiting and also restlessness and confusion.

#### **Pre-treatment checks**

- Avoid in comatose states, CNS depression, Parkinson disease, lesions of basal ganglia, clinically significant cardiac disorders, QTc interval prolongation, history of ventricular arrhythmias or torsade de pointes, µpulse or second- or third-degree heart block.
- Do not give with other QT prolonging drugs or to patients with uncorrected ↓K.
- Caution in patients with liver disease, renal failure, phaeochromocytoma, epilepsy, and conditions predisposing to epilepsy (e.g. alcohol withdrawal and brain damage) or convulsions.
- · Use with great caution in patients with disturbed thyroid function.
- When using for rapid tranquillisation, an antimuscarinic medication such as procyclidine or benzatropine should be available to treat any dystonia or EPSE.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| ECG                           | Renal function: U, Cr, CrCl (or eGFR) |
|-------------------------------|---------------------------------------|
| Electrolytes: serum K, Ca, Mg | TFTs                                  |
| LFTs                          |                                       |

#### Dose

Bioavailability from the oral route is about 60% of that from the IM route, and adjustment of dose may be required.

**Control of acutely agitated patients with moderate symptoms**: 2–10 mg by IM injection. Depending on response subsequent doses may be given every 4–6 hours, up to a maximum of 18 mg/day.

#### Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

| Significant interactions           | <ul> <li>The following may <i>î</i>haloperidol levels or effect (or <i>î</i>side-effects):<br/>antiarrhythmics, CNS depressants, buspirone, fluoxetine, quinidine.</li> <li>The following may <i>î</i>haloperidol levels or effect: enzyme-inducing drugs<br/>such as carbamazepine, phenobarbital and rifampicin.</li> </ul>                                                                                                                                                                |  |  |
| Action in case of overdose         | Antidote: None specific. A patent airway should be established and maintained. In view of isolated reports of arrhythmia, ECG monitoring is strongly advised.<br>JBP and circulatory collapse should be treated by plasma volume expansion and other appropriate measures. Adrenaline should not be used. Monitor body temperature and adequate fluid intake should be maintained. In cases of severe EPSE, appropriate antimuscarinic medication should be administered, e.g. procyclidine. |  |  |

SPC Haldol (accessed 3 October 2007).

# Haloperidol decanoate

#### 50 mg/mL and 100 mg/mL oily solution in 1-mL ampoules

This preparation is a depot preparation and must not be confused with haloperidol injection for rapid tranquillisation.

- · Haloperidol decanoate is a butyrophenone antipsychotic presented as a long-acting depot injection.
- It is used in the treatment of schizophrenia and other psychoses.
- Doses are expressed in terms of the base: Haloperidol 100 mg ≅ 141 mg haloperidol decanoate.

#### **Pre-treatment checks**

 Do not administer to patients in comatose states, including alcohol, barbiturate or opiate poisoning or patients with Parkinson's disease.

- Caution if suffering from epilepsy, liver disease, renal failure, cardiac disease, depression, myasthenia gravis, prostatic hypertrophy, narrow-angle glaucoma, hypothyroidism, hyperthyroidism, phaeochromocytoma, severe respiratory disease or if there are risk factors for stroke.
- Concomitant treatment with other antipsychotics should be avoided.

#### Biochemical and other tests

| Blood pressure | LFTs |
|----------------|------|
| Bodyweight     | TFTs |
| ECG            | U&Es |
| FBC            |      |

#### Dose

Test dose: 50 mg to assess tolerability. Reduce dose to 12.5-25 mg for elderly patients.

**Maintenance dose**: repeat dose every 4 weeks, increasing if necessary by 50-mg increments to 300 mg every 4 weeks. Some patients may require higher doses. If fortnightly administration is preferred doses should be halved.

#### Intramuscular injection

#### Preparation and administration

- 1. Before use warm the ampoule in the hands to aid withdrawal of the contents.
- 2. Withdraw the required dose. Maximum volume to be administered at one site is 2 mL. Volumes >2 mL should be distributed between two injection sites.
- 3. Give by deep IM injection into the gluteal region. Aspirate before injection to avoid inadvertent intravascular injection. Rotate injection sites for subsequent injections.

# Hartmann's solution (sodium lactate compound, Ringer-lactate)

#### 500-mL and 1-L infusion bags

- Hartmann's solution is a crystalloid intravenous fluid that behaves like NaCl 0.9% but more closely mimics extracellular fluid.
- Each 1000 mL contains: sodium chloride 6 g, sodium lactate 3.2 g, potassium chloride 400 mg, calcium chloride 270 mg.
- It is used to replenish extracellular fluid in place of NaCl 0.9% to \risk of hyperchloraemic acidosis, particularly where fluid replacement is required over a prolonged period.
- · Table H1 shows the electrolyte content of different volumes of the solution.

| Iddle FI Electrolyte content of Flartmann's solution |        |         |  |  |
|------------------------------------------------------|--------|---------|--|--|
| Volume                                               | 500 mL | 1000 mL |  |  |
| Sodium (mmol)                                        | 65.5   | 131     |  |  |
| Potassium (mmol)                                     | 2.5    | 5       |  |  |
| Calcium (mmol)                                       | 1      | 2       |  |  |
| Bicarbonate, as lactate (mmol)                       | 14.5   | 29      |  |  |
| Chloride (mmol)                                      | 55.5   | 111     |  |  |

# Table H1 Electrolyte content of Hartmann's solution

#### **Pre-treatment checks**

- Use with caution in patients with *†BP*, heart failure, and peripheral or pulmonary oedema, renal impairment, and liver cirrhosis, pre-eclampsia, toxaemia of pregnancy or other conditions associated with Na retention.
- · Caution in patients receiving corticosteroids and in geriatric or postoperative patients.
- Bicarbonate-forming compounds should **not** generally be given in respiratory alkalosis or any condition where lactate levels are elevated.
- Lactate solutions should **not** be used in severe acidosis requiring immediate repletion of plasma bicarbonate as the production of bicarbonate from lactate is delayed for 1–2 hours after administration. They should **not** be used to treat lactic acidosis.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pH Electrolytes: serum Na, K, Ca

#### Dose

**Treatment or prevention of fluid depletion:** dose is dependent upon the age, weight, biochemistry and clinical condition of the patient. Normal fluid requirements are generally about 40 mL/kg/ 24 hours. The use of colloid solutions should be considered where plasma expansion is required owing to  $\uparrow$ losses.

#### Intravenous infusion

#### Preparation and administration

- 1. The infusion is pre-prepared for use. It should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 2. Give by IV infusion at the required rate.
- 3. Discard any unused portion. Do not reconnect partially used infusion containers.

| Technical information |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |  |  |  |

### **Bibliography**

SPC. 2010, Compound Sodium Lactate Intravenous Infusion BP (Hartman's) at http://www.baxterhealthcare.co.uk (accessed 3 May 2010).
# Heparin

1000 units/mL solution in 1-mL, 5-mL and 20-mL ampoules or vials 5000 units/mL solution in 1-mL and 5-mL ampoules or vials 25 000 units/mL in 0.2-mL and 1-mL ampoules or vials 1 unit/mL solution in NaCl 0.9% 500-mL infusion bag Flush: 10 units/mL solution in 5-mL ampoules; 100 units/mL solution in 2-mL ampoules

Heparin calcium has also been used for the prophylaxis and treatment of VTE in similar doses to heparin sodium.

- · Heparin sodium is an anticoagulant agent derived from animal mucosa.
- It may be given by continuous IV infusion in the treatment of VTE, i.e. PE and DVT, STEMI and also
  in the acute coronary syndromes: unstable angina and NSTEMI, particularly where \renal function
  precludes the use of some LMWHs.
- It is used for prophylaxis of VTE in surgical and medical patients and to prevent thrombus formation in extracorporeal circulation during haemodialysis.
- · It may be used to maintain patency of central intravenous lines.
- Not all products are licensed for all indications.

## **Pre-treatment checks**

- · Do not use in patients who are haemorrhaging.
- Use extreme care in those at serious risk of haemorrhage, e.g. in cases of haemorrhagic blood disorders, thrombocytopenia, peptic ulcer disease, cerebrovascular disorders, bacterial endocarditis, severe *†BP*, oesophageal varices, or after recent surgery where haemorrhage remains a risk.
- · Caution in hepatic and renal impairment, and in elderly patients.

#### Biochemical and other tests

| Electrolytes: serum K | Renal function: U, Cr, CrCl (or eGFR)   |
|-----------------------|-----------------------------------------|
| Platelet count        | Treatment dose only: APTT or APTT ratio |

#### Dose

#### Prophylaxis

**General or orthopaedic surgery with high risk of VTE:** 5000 units by SC injection 2 hours preoperatively and then every 8–12 hours until the patient is mobile.

VTE prophylaxis in other patients: 5000 units SC every 8-12 hours.

#### Treatment

**Standard dose using heparin by IV infusion:** 5000 units by IV injection (for major PE give 10 000 units) followed by 18 units/kg/hour\* by IV infusion adjusting to APTT or APTT ratio.

- Omit the loading dose if initial APTT ratio is 1.5-2.5.
- If initial APTT ratio is > 2.5 review the need to start therapy.

\*Many hospitals use an initial rate of 1000 units/hour for all patients, then check APTT or APTT ratio after 2–6 hours and adjust rate accordingly. Table H2 is an example of a dose adjustment protocol – check local policy.

 Table H2
 An example of a dose adjustment protocol for heparin infusion using 50 000 units in a 50-mL syringe pump, i.e. 1000 units/mL.

Goal of therapy: therapeutic APTT of 50-70 seconds (for control 26-36 seconds); APTT ratio  $\cong 1.6\text{-}2.2$ 

| APTT<br>(seconds)<br>Control 26–36<br>seconds | APTT<br>ratio | Further<br>IV dose<br>(units) | Stop<br>infusion<br>(minutes) | Rate<br>change<br>(mL/hour) | Repeat<br>APTT<br>(hours) |

| >200                                          | >6.5°         | 0                             | 180 minutes                   | -0.4 mL/hour                | 3 hours                   |

<sup>a</sup>Seek medical advice and consider reversal with protamine sulfate if at risk of bleeding or oozing blood from drain sites or puncture sites (see the Protamine sulfate monograph).

#### Flushes and locks

As there are risks of repeated exposure to heparin and the risk of dosing errors, the use of heparin solutions for flushing or locking peripheral cannulas is not recommended.<sup>1</sup>

Choice of solution concentration and volume for central line lock varies according to the IV device used and local policies.

Dose in hepatic impairment: reduce dose in severe liver disease.

### Continuous intravenous infusion via a syringe pump

Preparation and administration

Make sure you have selected the correct strength of heparin injection.

- 1. Withdraw 50 mL of pre-prepared solution containing 1000 units/mL into a suitable syringe.\*
- The solution should be clear and colourless to pale straw in colour. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion using a syringe pump. Adjust dose to clinical response.

\*Alternatively, if a pre-prepared solution containing 1000 units/mL is not available, then withdraw 50 000 units (ensure you have selected the correct strength of injection) and make up to 50 mL with NaCl 0.9% in a syringe pump. This gives a solution containing 1000 units/mL. Diluted solutions must always be inverted at least 6 times during mixing to ensure thorough distribution of drug.

### 416 | Heparin

## **Subcutaneous injection**

Preparation and administration

Make sure you have selected the correct strength of heparin injection.

- 1. Withdraw the required dose.
- 2. The patient should be seated or lying down.
- 3. Pinch up a skin fold on the abdominal wall between the thumb and forefinger and hold throughout the injection.
- 4. Give by deep SC injection into the thick part of the skin fold at right angles to the skin. Do not rub the injection site after administration. Alternate doses between the right and left sides.

## **Intravenous injection**

Preparation and administration

Make sure you have selected the correct strength of heparin injection.

- 1. Withdraw the required dose.
- 2. The solution should be clear and colourless to pale straw in colour. Inspect visually for particulate matter or discoloration prior to administration.
- 3. Give by IV injection over 3-5 minutes.

# Hyaluronidase

#### 1500-unit dry powder ampoules

- · Hyaluronidase is an enzyme that makes body tissue more permeable to injected fluids.
- It may be used to enhance the absorption of SC fluids, local anaesthetics and SC or IM injections and to promote the resorption of excess fluids and blood in the tissues.

### **Pre-treatment checks**

- Do not use to reduce the swelling of bites or stings, or for anaesthetic procedures in unexplained premature labour.
- Ensure that the site selected for administration is healthy, clean, non-oedematous and convenient for the patient's comfort.

### Dose

Hyaluronidase must not be used with IV injections.

With SC infusions (hypodermoclysis): 1500 units by SC injection or injected into the tubing of the infusion site. This is sufficient for administration of 500–1000 mL of most fluids. (NB: in the USA the usual dose is 150 units/1000 mL of fluid.)

With SC or IM injections: 1500 units dissolved directly in solution to be injected (check compatibility).

**Extravasation:** where dispersal rather than localisation is indicated, 1500 units infiltrated into affected area (as soon as possible after extravasation is noticed).

Haematoma: 1500 units infiltrated into the affected area.

## With subcutaneous infusions

Care should be taken to control the speed and total volume of fluid administered and to avoid over-hydration, especially in renal impairment.

#### Preparation and administration

- 1. Dissolve 1500 units in 1 mL WFI or NaCl 0.9%.
- 2. Give by SC injection into the site before the infusion is set up. Alternatively, it may be injected into the tubing of the infusion set (about 2 cm back from the needle) at the start of the infusion.

### With subcutaneous or intramuscular injections

Preparation and administration

- 1. Dissolve 1500 units directly in the solution to be injected (check compatibility).
- 2. Give immediately by SC or IM injection as appropriate.

#### **Extravasation or haematoma**

- 1. Dissolve 1500 units in 1 mL of WFI or NaCl 0.9%.
- 2. Infiltrate into the affected area.

|                    |                                                                                  |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

## Bibliography

SPC Hyalase (accessed 12 December 2008).

# Hydralazine hydrochloride

#### 20-mg dry powder ampoules

- 1. Hydralazine is a vasodilator acting mainly on the arterioles to lower peripheral resistance and ↓arterial BP.
- The injection is used in management of hypertension with renal complications and hypertensive emergencies particularly those associated with pre-eclampsia and toxaemia of pregnancy.

## **Pre-treatment checks**

- Avoid in patients with idiopathic systemic lupus erythematosus, severe *pulse*, high output heart failure, myocardial insufficiency due to mechanical obstruction, cor pulmonale, dissecting aortic aneurysm; acute porphyria.
- · Patients with recent myocardial infarction should not receive hydralazine.
- Patients with suspected or confirmed coronary artery disease should only be given hydralazine under cover of a beta-blocker, which should be commenced a few days before treatment with hydralazine.
- · Caution in renal and hepatic impairment.

Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure and pulse LFTs Renal function: U, Cr, CrCl (or eGFR)

#### Dose

**Hypertensive crisis:** 5–10 mg by IV injection repeated if necessary after 20–30 minutes. Alternatively, give 200–300 micrograms/minute by continuous IV infusion. The rate should be titrated to response and maintenance rate is usually within 50–150 micrograms/minute.

The IM route is unlicensed in the UK, but doses of 10–50 mg have been used in the USA.

**Dose in renal impairment:** if CrCl < 30 mL/minute, the dose or dose interval should be adjusted according to clinical response.

**Dose in hepatic impairment:** the dose or dose interval should be adjusted according to clinical response.

#### Intravenous injection

#### Preparation and administration

- 1. Reconstitute each 20-mg ampoule with 1 mL WFI to give a solution containing 20 mg/mL.
- 2. Withdraw the required dose and further dilute to 10 mL with NaCl 0.9%.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over 2-3 minutes.

## Continuous intravenous infusion (large-volume infusion)

#### Preparation and administration

- 1. Reconstitute each 20-mg ampoule with 1 mL WFI to give a solution containing 20 mg/mL.
- Withdraw the required dose and add to a suitable volume of NaCl 0.9% (e.g. 20 mg/500 mL gives a solution containing 40 micrograms/mL). Mix well.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- Give by IV infusion via a volumetric infusion device at an initial rate of 200–300 micrograms/ minute, i.e. 5–7.5 mL/minute (300–450 mL/hour) of a 20 mg/500 mL infusion. Adjust the dose to the clinical response.

## Continuous intravenous infusion via a syringe pump

#### Preparation and administration

- 1. Reconstitute each 20-mg ampoule with 1 mL WFI to give a solution containing 20 mg/mL.
- 2. Make 60 mg (3 mL) up to 60 mL in a syringe pump with NaCl 0.9%.
- 3. Cap the syringe and mix well to give a solution containing 1 mg/mL.
- 4. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by IV infusion at an initial rate of 200–300 micrograms/minute, i.e. 0.2–0.3 mL/minute (12–18 mL/hour) of a 1 mg/mL solution. Adjust dose to clinical response.

## Intramuscular injection (unlicensed)

- 1. Reconstitute each 20-mg ampoule with 1 mL WFI.
- 2. Withdraw the required dose.
- 3. Give immediately by IM injection.

## Additional information

| Common and serious<br>undesirable effects | Injection/infusion-related: Local: Pain.<br>Common: ↓BP, ↑pulse, palpitation, angina symptoms, flushing, headache,<br>dizziness. Rarely hypersensitivity reactions (e.g. rash, pruritus, urticaria,<br>eosinophilia), development of SLE-like condition after long-term therapy.                                                                                                                                       |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pharmacokinetics                          | Elimination half-life is 2-3 hours but is up to 16 hours in severe renal failure (CrCl <20 mL/minute) and shortened to <1 hour in rapid acetylators.                                                                                                                                                                                                                                                                   |
| Significant<br>interactions               | <ul> <li>The following may          <sup>\hydralazine levels or effect (or          <sup>\hydralazine levels or effect): other         antihypertensives, anaesthetics tricyclic antidepressants, major tranquillisers         or drugs exerting central depressant actions (including alcohol) -         administration shortly before or after diazoxide may give rise to marked          BP.</sup></sup></li> </ul> |
| Action in case of<br>overdose             | Symptoms to watch for: <i>JBP</i> , <i>pulse</i> , myocardial ischaemia, dysrhythmias and coma.<br>Antidote: No known antidote; stop administration and give supportive therapy as appropriate. Use of adrenaline should be avoided.                                                                                                                                                                                   |
| Counselling                               | Patients should report chest pain and pain at injection site.<br>Warn of symptoms of vasodilatation such as flushing and dizziness.                                                                                                                                                                                                                                                                                    |

## **Bibliography**

SPC Apresoline injection (accessed 24 August 2009).

# Hydrocortisone acetate

#### 25 mg/mL aqueous suspension in 1-mL ampoules

- · Hydrocortisone acetate is a corticosteroid formulated for local use only.
- It is given by intra-articular or periarticular injection to treat arthritic conditions when few joints are involved.
- It may also be used for the symptomatic treatment of some non-articular inflammatory conditions, e.g. inflamed tendon sheaths and bursas.

### **Pre-treatment checks**

- · Do not inject into unstable joints.
- · Do not give in the presence of active infection in or near joints.
- Prior to administration of hydrocortisone acetate a local anaesthetic may be infiltrated into the soft tissue surrounding the joint and/or injected into the joint or mixed in the same syringe (unlicensed).

#### Biochemical and other tests

Early morning stiffness ESR and CRP Number of tender or swollen joints Pain

### Dose

**Standard dose:** 5–50 mg by intra-articular or periarticular injection depending on size of joint. Do not treat more than three joints in one day. The injection may be repeated at intervals of about 3 weeks.

### Intra-articular or periarticular injection

- 1. Withdraw the required dose.
- 2. Give by the desired route.

## Additional information

| Common and serious<br>undesirable effects | Injection-related: Intra-articular: Temporary local exacerbation with increased<br>pain and swelling. This normally subsides after a few hours.<br><i>Systemic:</i> Systemic undesirable effects are unlikely but may occur after high or<br>prolonged local dosage: †BP, Na and water retention, ↓K, ↓Ca, †blood<br>glucose, peptic ulceration and perforation, psychiatric reactions, †susceptibility<br>to infection, muscle weakness, tendon rupture, insomnia, †intracranial pressure,<br>↓seizure threshold, impaired healing. For undesirable effects resulting from<br>long-term corticosteroid use refer to the BNF. |
|-------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pharmacokinetics                          | Absorption after local injection is very slow and is usually completed 24-48 hours after intra-articular injection.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Significant<br>interactions               | A small number of local injections are unlikely to have any significant interactions typical of corticosteroids.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Action in case of overdose                | Overdose is very unlikely, treatment should be symptomatic.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Counselling                               | Patients on long-term corticosteroid treatment should read and carry a Steroid Treatment Card.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## **Bibliography**

SPC Hydrocortistab (accessed 27 June 2009).

# Hydrocortisone sodium phosphate

#### 100 mg/mL solution in 1-mL and 5-mL ampoules

- Hydrocortisone sodium phosphate is a corticosteroid with both glucocorticoid and, to a lesser extent, mineralocorticoid activity.
- It is used in the treatment of conditions for which systemic corticosteroid therapy is indicated.
- It is used parenterally when a rapid effect is required in emergencies, e.g. acute adrenocortical insufficiency, and also when the oral route is temporarily unavailable or inappropriate.
- It may also be given by soft-tissue injection for various inflammatory conditions.
- Doses are expressed in terms of the base: Hydrocortisone 100 mg ≅ 134 mg hydrocortisone sodium phosphate.

### **Pre-treatment checks**

- · Avoid where systemic infection is present (unless specific therapy is given).
- · Avoid live virus vaccines in those receiving immunosuppressive doses.
- May activate or exacerbate amoebiasis or strongyloidiasis (exclude before initiating a corticosteroid in those at risk or with suggestive symptoms). Fungal or viral ocular infections may also be exacerbated.
- Caution in patients predisposed to psychiatric reactions, including those who have previously suffered corticosteroid-induced psychosis, or who have a personal or family history of psychiatric disorders.
- Do not use in the treatment of cerebral oedema associated with acute head injury or cerebrovascular accident, as it is unlikely to be of benefit and may even be harmful.

Biochemical and other tests (not all are necessary in an emergency situation)

Electrolytes: serum Na, K, Ca

## Dose

**Standard dose:** 100–500 mg by IV injection/infusion or IM injection depending upon the condition being treated. The dose may be repeated 3–4 times in 24 hours as determined by the patient's response.

**Injection into soft tissues:** 100–200 mg daily; may be repeated on 2–3 occasions depending upon the patient's response.

## **Intravenous injection**

Preparation and administration

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over a minimum of 30-60 seconds.

## Intermittent intravenous infusion

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Add to a convenient volume of compatible infusion fluid.
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 20-30 minutes.

## Intramuscular injection

- 1. Withdraw the required dose.
- 2. Give by IM injection.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

## **Bibliography**

SPC Efcortesol injection (accessed 9 September 2009).

# Hydrocortisone sodium succinate

#### 100-mg dry powder vials

- Hydrocortisone sodium succinate is a corticosteroid with both glucocorticoid and, to a lesser extent, mineralocorticoid activity.
- It is used in the treatment of conditions for which systemic corticosteroid therapy is indicated.
- It is used parenterally when a rapid effect is required in emergencies, e.g. acute adrenocortical insufficiency, and also when the oral route is temporarily unavailable or inappropriate.
- Doses are expressed in terms of the base: Hydrocortisone 100 mg ≅ 134 mg hydrocortisone sodium succinate.

#### **Pre-treatment checks**

- Avoid where systemic infection is present (unless specific therapy given).
- · Avoid live virus vaccines in those receiving immunosuppressive doses.
- May activate or exacerbate amoebiasis or strongyloidiasis (exclude before initiating a corticosteroid in those at risk or with suggestive symptoms). Fungal or viral ocular infections may also be exacerbated.
- Caution in patients predisposed to psychiatric reactions, including those who have previously suffered corticosteroid-induced psychosis, or who have a personal or family history of psychiatric disorders.
- Do not use in the treatment of cerebral oedema associated with acute head injury or cerebrovascular accident, as it is unlikely to be of benefit and may even be harmful.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Electrolytes: serum Na, K, Ca

#### Dose

**Standard dose:** 100–500 mg given by IM injection or by IV injection or infusion. The dose depends on the severity of the condition and may be repeated at intervals of 2, 4 or 6 hours as indicated by the patient's response and clinical condition.

### Intravenous injection

#### Preparation and administration

- 1. Reconstitute each vial with 2 mL WFI to give a solution containing 100 mg/2 mL.
- 2. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV injection over 1-10 minutes.

## Intermittent intravenous infusion

#### Preparation and administration

- 1. Reconstitute each vial with 2 mL WFI to give a solution containing 100 mg/2 mL.
- 2. Withdraw the required dose and add to a minimum of 100 mL of compatible infusion fluid.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 4. Give by IV infusion over 20-30 minutes.

**Fluid-restricted patients:** the required dose has been given in 50 mL NaCl 0.9% or Gluc 5% (unlicensed).

## Intramuscular injection

- 1. Reconstitute each vial with up to 2 mL WFI then shake to form a solution.
- 2. Withdraw the required dose
- 3. Give by IM injection.

| Technical information |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |  |

SPC Solucortef (accessed 9 September 2009).

# Hydroxocobalamin (vitamin B<sub>12</sub>)

#### 1 mg/mL solution in 1-mL ampoules

- Vitamin B<sub>12</sub>, a water soluble vitamin, occurs in the body in various forms including hydroxocobalamin. Deficiency may occur in strict vegetarians, in patients with malabsorption syndromes or metabolic disorders, or in patients following gastrectomy or extensive ileal resection. Deficiency results in megaloblastic anaemias, demyelination and other neurological damage.
- Hydroxocobalamin is used to treat pernicious anaemia, for prophylaxis and treatment of other macrocytic anaemias associated with vitamin B<sub>12</sub> deficiency and to treat tobacco amblyopia and Leber's optic atrophy.
- Hydroxocobalamin may be used diagnostically as part of the Schilling test to assess absorption of vitamin B<sub>12</sub> if an absence of intrinsic factor is suspected.
- Hydroxocobalamin may also be used as an emergency treatment for cyanide poisoning (unlicensed indication). The standard hydroxocobalamin preparation is not suitable for this use. Cyanokit, an imported product that contains 2.5 g hydroxocobalamin per vial, is manufactured for this indication.

## **Pre-treatment checks**

Do not use for the treatment of megaloblastic anaemia of pregnancy unless a definite diagnosis of vitamin  $B_{12}$  deficiency has been established.

Biochemical and other tests (not all are necessary in an emergency situation)

Electrolytes: serum K (cardiac arrhythmias secondary to  $\downarrow$ K during initial therapy have been reported – correct if necessary).

FBC

Serum folate (to ensure that folate deficiency is not a contributory/causative factor).

A baseline assessment of neurological function is useful to assess impact of treatment in cases of vitamin  $B_{12}$  deficiency anaemia with neurological complications.

#### Dose

**Pernicious anaemia and other macrocytic anaemias without neurological involvement**: initially 1 mg by IM injection 3 times a week for 2 weeks then 1 mg every 3 months.

**Pernicious anaemia and other macrocytic anaemias with neurological involvement**: initially 1 mg by IM injection on alternate days until there is no further improvement, then 1 mg every 2 months.

**Prophylaxis of macrocytic anaemias associated with vitamin B<sub>12</sub> deficiency**: 1 mg by IM injection every 2–3 months.

**Tobacco amblyopia and Leber's optic atrophy**: initially 1 mg by IM injection daily for 2 weeks, then 1 mg twice weekly until there is no further improvement, then 1 mg every 1–3 months. **Schilling test**: involves use of IM hydroxocobalamin as part of the test.

## Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

## Hyoscine butylbromide (scopolamine butylbromide)

20 mg/mL solution in 1-mL ampoules

This preparation must not be confused with hyoscine hydrobromide.

- Hyoscine butylbromide is quaternary ammonium derivative with antimuscarinic activity.
- It is used to relieve smooth-muscle spasm in GI and genitourinary disorders.
- It is licensed for use in radiology for differential diagnosis of obstruction and to reduce spasm and pain in diagnostic procedures where spasm may be a problem.
- Hyoscine butylbromide may also be given (unlicensed) by SC infusion in palliative care to reduce
  excessive respiratory secretions and relieve bowel colic.
- · Doses are expressed as hyoscine butylbromide.

### **Pre-treatment checks**

- Do not give in myasthenia gravis (but may be used to ↓muscarinic side-effects of anticholinesterases), megacolon, narrow-angle glaucoma, ↑pulse, prostatic enlargement with urinary retention, mechanical stenoses in the region of the GI tract or paralytic ileus.
- Caution in Down's syndrome, in children and in elderly patients, in GORD, diarrhoea, ulcerative colitis, acute MI, *†BP*, conditions characterised by *†pulse* (including hyperthyroidism, cardiac insufficiency, cardiac surgery), pyrexia (may reduce sweating), pregnancy and breast feeding, and in individuals susceptible to angle-closure glaucoma.
- · It is considered unsafe in porphyria.

#### Biochemical and other tests

Blood pressure

#### Dose

Acute spasm and spasm in diagnostic procedures: 20 mg by IM or slow IV injection repeated after 30 minutes if necessary (may be repeated more frequently in endoscopy) up to a maximum of 100 mg daily.

### Intramuscular injection

- 1. Withdraw the required dose.
- 2. Inject into a large muscle such as the gluteus or the lateral aspect of the thigh.

## Intravenous injection

- 1. Withdraw the required dose.
- 2. The solution should be clear and colourless or almost colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 3–5 minutes. May be diluted to 10 mL with NaCl 0.9% or Gluc 5% to enable slow administration if necessary.

# Hyoscine hydrobromide (scopolamine hydrobromide)

#### 400 micrograms/mL and 600 micrograms/mL solution in 1-mL ampoules

This preparation must not be confused with hyoscine butylbromide.

- Hyoscine hydrobromide is a tertiary amine with antimuscarinic activity.
- It is used as a preoperative medication to control bronchial, nasal, pharyngeal and salivary secretions. It also helps to prevent bronchospasm and laryngospasm and blocks cardiac vagal inhibiting reflexes during induction of anaesthesia and intubation. It can provide a degree of amnesia, sedation and antiemesis.
- Hyoscine hydrobromide may also be given (unlicensed) by SC injection or infusion in palliative care to reduce excessive respiratory secretions.
- · Doses are expressed as hyoscine hydrobromide.

### **Pre-treatment checks**

- · Avoid in narrow-angle glaucoma.
- Caution in cardiovascular disease, gastrointestinal obstruction, paralytic ileus, prostatic enlargement, Down's syndrome, myasthenia gravis, renal or hepatic impairment.

#### Biochemical and other tests

Blood pressure

#### Dose

**Premedication**: 200–600 micrograms by SC or IM injection 30–60 minutes before induction of anaesthesia. In acute use the injection may also be administered by IV injection.

**Excessive respiratory secretions** (unlicensed): 400–600 micrograms by SC injection every 4–8 hours, taking care to avoid discomfort caused by dry mouth. Hyoscine hydrobromide may also be given by SC infusion.

## **Subcutaneous injection**

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by SC injection.

## Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection.

## **Intravenous injection**

#### Preparation and administration

- 1. Withdraw the required dose and dilute to a suitable volume with WFI.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection.

## **Bibliography**

SPCs Hyoscine hydrobromide 400 and 600 micrograms/mL solution for injection, Wockhardt UK Ltd (accessed 11 June 2008).

# Ibandronic acid

#### 1 mg/mL solution in 2-mL ampoules and 6-mL vials (Bondronat) 1 mg/mL solution in 3-mL pre-filled syringe (Bonviva)

- Ibandronate is an aminobisphosphonate that is a potent inhibitor of bone resorption.
- Bondronat is indicated for prevention of skeletal events (pathological fractures, bone complications requiring radiotherapy or surgery) in patients with breast cancer and bone metastases and for treatment of tumour-induced ↑Ca with or without metastases.
- Bonviva is indicated for treatment of osteoporosis in postmenopausal women at increased risk of fracture.
- Doses are expressed in terms of the base: Ibandronic acid 1 mg = 1.125 mg ibandronic acid monosodium salt, monohydrate.

### **Pre-treatment checks**

- · Do not give to patients already receiving other bisphosphonates.
- Osteonecrosis of the jaw can occur: consider dental examination and preventive dentistry prior to
  planned treatment in patients with risk factors (e.g. cancer, chemotherapy, radiotherapy, corticosteroids, poor oral hygiene). Avoid invasive dental procedures during treatment if possible.
- Give cautiously to patients who have had previous thyroid surgery (increased risk of ↓Ca)
- Contraindicated in pregnancy. Women of child-bearing potential should take contraceptive precautions during *planned* treatment.
- Unless it is being used for *Ca*, prescribe oral calcium and vitamin D supplements in those at risk of deficiency (e.g. through malabsorption or lack of exposure to sunlight). All patients being treated for osteoporosis should receive supplements.
- Hydrate patient adequately before, during and after infusions (up to 4L may be given over 24 hours, but over-hydration should be avoided; risk of cardiac failure).

#### Biochemical and other tests

Electrolytes: serum Na, K, Ca, PO<sub>4</sub>, Mg Renal function: U, Cr, CrCl (or eGFR)

### Dose

## **Prevention of skeletal events in breast cancer and bone metastases (Bondronat):** 6 mg by IV infusion every 3–4 weeks.

**Dose for this indication in renal impairment:** adjusted according to creatinine clearance, see Table I1.

| Table 11         Ibandronic acid dose in renal impairment |             |                                 |                         |  |  |  |  |
|-----------------------------------------------------------|-------------|---------------------------------|-------------------------|--|--|--|--|
| Creatinine<br>clearance (mL/<br>minute)                   | Dosage (mg) | Minimum duration<br>of infusion | Infusion volume<br>(mL) |  |  |  |  |
| ≥50                                                       | 6 mg        | 15 minutes                      | 100 mL                  |  |  |  |  |
| 30-49                                                     | 6 mg        | 1 hour                          | 500 mL                  |  |  |  |  |
| <30                                                       | 2 mg        | 1 hour                          | 500 mL                  |  |  |  |  |

#### Treatment of tumour-induced hypercalcaemia (Bondronat):

The patient must be adequately hydrated using NaCl 0.9% before dosing for *\Ca.* 

Dependent on the patient's initial 'corrected' serum Ca; see Table I2. Normalisation of serum Ca is usually seen within 7 days. If normocalcaemia is not achieved within this time, a further dose may be given. The duration of the response varies – treatment can be repeated whenever ↑Ca recurs.

| Table 12         Treatment of tumour-induced hypercalcaemia with ibandronic acid |         |           |                                    |             |  |  |  |
|----------------------------------------------------------------------------------|---------|-----------|------------------------------------|-------------|--|--|--|
| Initial serum calcium ('corrected')                                              |         | Dose (mg) | Minimum                            | Infusion    |  |  |  |
| (mmol/L)                                                                         | (mg/dL) |           | duration of<br>infusion<br>(hours) | volume (mL) |  |  |  |
| <3.0                                                                             | <12.0   | 2 mg      | 2 hours                            | 500 mL      |  |  |  |
| ≥3.0                                                                             | ≥12.0   | 4 mg      | 2 hours                            | 500 mL      |  |  |  |

**Treatment of osteoporosis in postmenopausal women at increased risk of fracture (Bonviva):** 3 mg by IV injection every 3 months. Do not give more often than every 3 months. Do not give for this indication if CrCl <30 mL/minute.

## Intravenous infusion (Bondronat)

Preparation and administration

Ibandronic acid is incompatible with Hartmann's and Ringer's (contain Ca).

- 1. Withdraw the required dose and add to the appropriate volume of NaCl 0.9% or Gluc 5% (dependent on renal function and indication see information above).
- 2. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion over the appropriate period of time (dependent on renal function and indication see information above).

## Intravenous injection (Bonviva)

- 1. Bonviva is supplied as a pre-filled syringe containing 3 mg/3 mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 15–30 seconds.

| Technical information       |                                                                                                                                                                               |

# lloprost

100 micrograms/mL solution in 1-mL ampoules

lloprost must not be confused with its analogue epoprostenol (both names are sometimes erroneously used interchangeably).

- Iloprost trometamol is a synthetic analogue of epoprostenol that causes vasodilatation and has platelet de-aggregant properties.
- It is given by IV infusion (as an unlicensed product) to treat peripheral vascular disease and pulmonary hypertension.

- Many centres have their own protocols for dosing and handling iloprost by infusion and these should be followed where available.
- Iloprost trometamol is also given via nebuliser to treat idiopathic or familial pulmonary arterial hypertension, for which a licensed product exists.
- Doses are expressed in terms of the base: Iloprost 1 nanogram ≅ 1.3 nanograms iloprost trometamol.

#### **Pre-treatment checks**

- Caution in concomitant anticoagulant therapy or drugs that ↑risk of bleeding.
- · Caution in hepatic and renal impairment.

Biochemical and other tests (not all are necessary in an emergency situation)

| Blood pressure | LFTs                  |
|----------------|-----------------------|
| Bodyweight     | Renal function: U, Cr |
| Heart rate     |                       |

#### Dose

**Peripheral vascular disease (unlicensed):** 0.5–2 nanograms/kg/minute for 6 hours daily by IV infusion. Up to 4 weeks of treatment may be required.

**Primary pulmonary hypertension (unlicensed):** 1–8 nanograms/kg/minute for 6 hours daily. Alternatively, iloprost may be given via nebuliser (licensed product) at a dose of 2.5–5 micrograms inhaled 6–9 times daily.

**Dose in renal or hepatic impairment:** in liver cirrhosis or in renal impairment requiring dialysis the dose may need to be halved.

Calculation of infusion rate (see also Table I3):

 $Infusion \ rate \ (mL/hour) = \frac{Dose \ (nanograms/kg/minute) \times bodyweight \ (kg) \times 60}{Concentration \ of \ infusion \ (nanograms/mL)}$

## Table 13 Iloprost rate of infusion using a 2000 nanograms/mL solution

## 444 | lloprost

## Continuous intravenous infusion via syringe pump

#### Preparation of a 2000 nanograms/mL solution

- 1. Withdraw 100 micrograms (1 mL) and make up to 50 mL in a syringe pump with NaCl 0.9% or Gluc 5%.
- 2. Cap the syringe and mix well to give a solution containing 2000 nanograms/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

Give by continuous IV infusion at the required rate. If adverse effects occur stop the infusion and review; may be recommenced after 1 hour at half the previous rate if appropriate.

| Technical information       |                                                                                                                |  |

# Imipenem with cilastatin

### 500-mg dry powder vials

- Imipenem is a semisynthetic carbapenem beta-lactam antibacterial that is always given with cilastatin (which inhibits the renal metabolism of imipenem) in a ratio of 1:1 by weight.
- It is used for infections caused by susceptible organisms including infections in neutropenic patients, intra-abdominal infections, bone and joint infections, skin and soft-tissue infections, urinary tract infections, biliary tract infections, hospital-acquired pneumonia, and septicaemia.
- It may also be used for surgical infection prophylaxis and as part of a multidrug regimen for the treatment of anthrax.
- Doses are expressed as milligrams of imipenem.

## **Pre-treatment checks**

- Do not give if there is known hypersensitivity to any carbapenem antibacterial agent or cilastatin, or previous immediate hypersensitivity reaction to penicillins or cephalosporins.
- Caution in CNS disorders (e.g. epilepsy).

#### Biochemical and other tests

FBC LFTs Renal function: U, Cr, CrCl (or eGFR)

## Dose

Mild infections: 250 mg by IV infusion every 6 hours.

Moderate infections: 500 mg by IV infusion every 8 hours.

Severe, fully susceptible infections: 500 mg by IV infusion every 6 hours.

**Severe and/or life-threatening infections** due to less sensitive organisms (primarily some strains of *P. aeruginosa*): 1 g by IV infusion every 6–8 hours.

**Surgical prophylaxis**: 1 g by IV infusion at induction repeated after 3 hours, supplemented in high risk (e.g. colorectal) surgery by doses of 500 mg at 8 and 16 hours after induction. Check local policies. **Dose in renal impairment**: adjusted according to creatinine clearance:

- CrCl 31-70 mL/minute: 500 mg every 6-8 hours.
- CrCl 21-30 mL/minute: 500 mg every 8-12 hours.
- CrCl 6–20 mL/minute: 250 mg (or 3.5 mg/kg, whichever is the lower) every 12 hours or occasionally 500 mg every 12 hours (†risk of convulsions).
- CrCl 5 mL/minute or less: should only be given if haemodialysis is started within 48 hours; 250 mg (or 3.5 mg/kg, whichever is the lower) should be given after a dialysis session and then every 12 hours.

## Intermittent intravenous infusion

Preparation and administration

Imipenem with cilastatin should not be directly mixed with Hartmann's (incompatible with lactate) but may be co-administered via Y-site.

- 1. Disperse the contents of each 500-mg vial in 10 mL NaCl 0.9% to produce a suspension of the drug.
- 2. Withdraw the required dose from the vial(s) and add to 100 mL NaCl 0.9%. If necessary use a further 10 mL NaCl 0.9% to effectively 'wash out' the vial (s) and add this to the infusion bag to ensure complete transfer of vial contents.
- 3. Agitate the bag to ensure complete mixing.
- 4. The solution should be clear and colourless to yellow. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by IV infusion. Give 250–500 mg over 20–30 minutes and 1 g over 40–60 minutes. The infusion rate should be slowed if the patient develops nausea during the infusion.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

## Bibliography

SPC Primaxin IV injection (accessed 23 March 2009).

# Infliximab

#### 100-mg dry powder vial

Infliximab should be used under specialist supervision only.

- Infliximab is a cytokine modulator.
- It is licensed for use in the treatment of rheumatoid arthritis, adult and paediatric Crohn's disease, ulcerative colitis, ankylosing spondylitis, psoriatic arthritis and psoriasis.
- If it is being used for any rheumatologic indication other than rheumatoid arthritis, ankylosing spondylitis or psoriatic arthritis, the patient should be entered on the British Society of Rheumatology's Biologics Register.<sup>1</sup>
- Infliximab has been assessed by NICE and in the UK should be used in accordance with the appropriate guidance.

## **Pre-treatment checks**

- Screen for tuberculosis, do not give to patients with active tuberculosis or other severe infections.
- Do not give to patients with moderate to severe heart failure.
- Monitor patients for hepatitis B virus, reactivation of hepatitis B has occurred in patients who are carriers.
- Caution should be exercised when using in patients with demyelinating CNS disorders since there
  is a risk of exacerbating clinical symptoms.
- If the patient has experienced infusion reactions, consider pretreatment with an antihistamine, hydrocortisone and/or paracetamol to prevent mild and transient effects.

#### Biochemical and other tests

| Bodyweight | LFTs                                              |
|------------|---------------------------------------------------|
| CRP        | Skin assessment (if being used for psoriasis)     |
| ESR        | Tender joint count, swollen joint count (if being |
| FBC        | used for psoriatic or rheumatoid arthritis)       |

#### Dose

**Rheumatoid arthritis**: initially 3 mg/kg by IV infusion, repeated at 2 and 6 weeks after the initial dose and then every 8 weeks thereafter.

**Severe active Crohn's disease**: initially 5 mg/kg by IV infusion, then 5 mg/kg 2 weeks after the initial dose. If the condition has responded, maintenance of *either* 5 mg/kg 6 weeks after initial dose, then 5 mg/kg every 8 weeks *or* a further dose of 5 mg/kg if signs and symptoms recur.

**Fistulating Crohn's disease**: initially 5 mg/kg by IV infusion, repeated at 2 and 6 weeks after the initial dose. If the condition has responded, consult product literature for guidance on further doses. **Moderate to severe active ulcerative colitis**: initially 5 mg/kg by IV infusion repeated at 2 and 6 weeks after the initial dose, then 5 mg/kg every 8 weeks; discontinue if there is no response 14 weeks after the initial dose.

**Ankylosing spondylitis**: initially 5 mg/kg by IV infusion, repeated at 2 and 6 weeks after the initial dose and then every 6–8 weeks. If there is no response at 6 weeks, no additional treatment with infliximab should be given.

**Psoriatic arthritis:** initially 5 mg/kg by IV infusion, repeated at 2 and 6 weeks after the initial dose, then every 8 weeks thereafter.

**Psoriasis:** initially 5 mg/kg by IV infusion, repeated at 2 and 6 weeks after the initial dose, then every 8 weeks thereafter. If there is no response after 14 weeks, no additional treatment with infliximab should be given.

### Intermittent intravenous infusion

Preparation and administration

The infusion should be prepared in a CIVAS unit.

- 1. Confirm the patient's details on the prepared bag, and that the correct dose has been supplied.
- The solution should be clear and almost colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion through a low-protein-binding filter (pore size 1.2 micron or less) over at least 2 hours.

# Insulins

#### Insulin 100 units/mL solution in 10-mL vials 3-mL pen cartridges and 3-mL pre-filled pens (see chart below) Restricted use: insulin 500 units/mL solution in 10-mL vials

- Insulin is a hormone produced by the pancreas that is crucial in the regulation of carbohydrate, protein and fat metabolism. It is secreted when blood glucose levels start to rise; its action is opposed by glucagon; catecholamines, glucocorticoids and growth hormone (the counter-regulatory hormones), and others. Decreased or absent insulin secretion results in the development of diabetes mellitus, although patients with insulin resistance may be markedly hyperinsulinaemic as well as hyperglycaemic.
- The main use of insulin is in the treatment of diabetes mellitus. For maintenance treatment it is given by SC injection (in various regimens) or by continuous SC insulin infusion (CSII).
- Soluble insulin is given by IV infusion in acute illness, e.g. DKA or HHS (formerly known as HONS or HONK), and for maintenance in patients who are temporarily unable to take food by mouth, e.g. perioperatively. The IM route may occasionally be used in the initial treatment of DKA and HHS as a stop-gap measure until IV infusion can be established, as absorption is thought to be slightly faster than via the SC route.
- Insulin is given (unlicensed) by IV infusion in the treatment of moderate to severe ↑K because it increases intracellular uptake of potassium. Glucose is given alongside to counteract hypoglycaemia.
- Rarely insulin containing 500 units/mL may be required for a specific patient. If used it must be kept completely separate from all other insulins, be clearly labelled, and only be administered by staff who have had specific training in its use.<sup>1</sup>
- Insulins were initially produced commercially from animal pancreases (pork and/or beef). Human sequence insulins are now widely available and are produced either by enzymatic modification of porcine insulin (emp), or biosynthetically by recombinant DNA technology using bacteria (crb, prb) or yeast (pyr).

## **Prescribing insulin**

- Soluble insulin is fairly rapidly absorbed from SC injection sites and insulin has therefore now been
  produced in many different formulations and types aimed at ↑ or ↓rate of absorption following SC
  injection. These are grouped according to onset and duration of action (see Table I4 below).
- Insulins should always be prescribed by brand name because release characteristics may vary even between insulins in the same category.
- Insulin doses are expressed in units. Insulin prescriptions should always state the word 'units' in full; the use of abbreviations such as 'U' or 'IU' has caused serious administration errors.<sup>1</sup>
- Insulin should always be measured using insulin syringes designed for the purpose. The use of
  other syringes has resulted in fatal dosing errors.<sup>1</sup>

#### **Pre-treatment checks**

- Should not be used in hypoglycaemia unless adequate glucose is given alongside.
- JVP, BP and pulse prior to treatment for DKA and HHS, to assess appropriate speed for necessary rehydration.

#### Biochemical and other tests (not all are necessary in an emergency situation)

| ABG (in DKA)                                    | Bodyweight in certain indications |
|-------------------------------------------------|-----------------------------------|
| Blood cultures (if infection suspected)         | FBC                               |
| Blood glucose (plus formal laboratory sample as | Plasma osmolality (in HHS)        |
| soon as possible in DKA and HHS)                | U&Es                              |
| Blood or urine ketones (in suspected DKA)       |                                   |

#### Dose

**Diabetic ketoacidosis:** DKA is a medical emergency and its management is complex. Insulin is used in combination with aggressive rehydration, potassium supplementation and many other supportive measures, alongside intensive monitoring.<sup>2</sup>

- Insulin is given by IV infusion via a syringe pump at a fixed rate of 0.1 unit/kg/hour using an
  insulin infusion containing 1 unit/mL (i.e. 7 mL/hour if weight is 70 kg). If there is a delay in
  setting up the IV infusion, then a single dose of 0.1 unit/kg may be given by IM injection.
- If the patient is normally maintained on *Lantus* or *Levemir* insulin by SC injection then this should be continued at the usual dose and usual time.
- As soon as the blood glucose falls to 14 mmol/L, give Gluc 10% initially at 125 mL/hour alongside other fluids so that hypoglycaemia is avoided.
- Once ketonaemia has resolved and the patient is biochemically stable and able to eat/drink, insulin by SC injection should be resumed or started. If the patient is unable to eat/drink see NBM management below.

**Hyperosmolar hyperglycaemic state:** HHS management varies from hospital to hospital. Insulin is used in combination with rehydration, potassium and other supportive measures, alongside intensive monitoring.

- Insulin is given as a variable-dose IV infusion (see Table 15 below) adjusted to reduce blood glucose levels by about 3 mmol/hour.
- Patients with HHS may be highly sensitive to insulin. Once the patient is biochemically stable and able to eat/drink, the usual therapy for diabetes treatment should be resumed or started. If the patient is unable to eat/drink, see NBM management below.

#### Control of blood glucose in patients who are perioperative or otherwise nil by mouth

**(NBM):** insulin should be given as a variable-dose infusion (see Table I5) with Gluc 5% or 10% alongside (including KCl unless  $\uparrow$ K) so that hypoglycaemia is avoided.

**Moderate to severe hyperkalaemia (unlicensed):** calcium gluconate is given to stabilise the myocardium (see Calcium gluconate monograph) followed by 5–10 units of soluble insulin with

50 mL Gluc 50% over 5–15 minutes. Effects are seen in 15 minutes and last 4–6 hours.<sup>3</sup> Repeat as necessary or give as a continuous infusion.

Maintenance regimens for insulin-dependent or insulin-requiring diabetes mellitus: the regimen chosen depends on the patient's ability to inject, monitor and adjust doses, patient preference and the degree of blood glucose control required. All regimens are given by SC injection with the exception of CSII.

- **Once daily:** usually given as a single daily dose of an intermediate or long-acting insulin. Occasionally a biphasic insulin is used, but the dose must then be given in association with a meal.
- **Twice daily:** usually given as a twice daily dose of an intermediate or biphasic insulin with breakfast and evening meal.
- **Basal-bolus:** an intermediate- or long-acting insulin is given once (or occasionally twice) daily to provide a background or 'basal' level of insulin; doses of a short- or rapid-acting insulin are given with food.
- Dose adjustment for normal eating (DAFNE): similar to basal-bolus but patients attend a 5day course on dose adjustment, and management of sickness.
- **CSII**: given via a programmable external pump containing an insulin reservoir. The pump is set to deliver a basal level of insulin by SC infusion and bolus doses are given using the pump to coincide with food intake.

Dose in renal impairment: reduced doses may be required in severe renal impairment.

#### **Subcutaneous injection**

#### Preparation and administration

- 1. Check that the insulin you have selected is the one specified on the prescription chart.
- 2. If using an insulin suspension, re-suspend by rolling the vial, cartridge or pen gently between the palms or inverting several times. The insulin suspension should look uniformly milky.
- Withdraw the required dose using an insulin syringe\*, or dial up the correct dose according to the manufacturer's instructions if using an insulin pen.
- 4. Using an area on the abdomen, outer thigh, upper outer arm or the buttock, pinch up a skin fold between the thumb and forefinger and hold throughout the injection.
- 5. Give by SC injection into the thick part of the skin fold at right angles to the skin. Leave the needle *in situ* for a few seconds before removal.
- 6. Do not rub the injection site after administration. Avoid overuse of injection sites as this may impair absorption; rotate sites so that individual sites are not reused within 1 month.

\*Some insulins may be mixed in the syringe immediately prior to administration – see individual product literature.

#### Continuous intravenous infusion via a syringe pump

This method is used for control of blood glucose. Only solutions containing 1 unit/mL should be prepared.<sup>1</sup>

#### Preparation and administration

- 1. Withdraw 49.5 mL NaCl 0.9% into a syringe suitable for use in a syringe pump.
- 2. Withdraw 50 units (0.5 mL) soluble insulin (e.g. Actrapid, Humulin S) into an insulin syringe and add to the prepared syringe.
- 3. Cap the syringe and mix well to give a solution containing 1 unit/mL.
- 4. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### 454 | Insulins

- 5. Give by IV infusion at the required rate.\* Check hydration status, patency of IV access and the pump for malfunction if blood glucose values are higher than expected at any point.
- 6. Prepare a fresh syringe at least every 24 hours if required.

\*If the patient is normally maintained on *Lantus* or *Levemir* insulin by SC injection then this should be continued at the usual dose and usual time while the insulin infusion is in progress.<sup>2</sup>

# Intravenous injection or infusion via a syringe pump (unlicensed use for hyperkalaemia only)

This method is used for the treatment of hyperkalaemia only. There are no stability data on insulin added to Gluc 50%; prepared syringes must be used immediately.

#### Preparation and administration

- 1. Withdraw 50 mL Gluc 50% into a syringe.
- 2. Withdraw the required dose of soluble insulin (e.g. Actrapid, Humulin S) into an insulin syringe and add to the prepared syringe.
- 3. Cap the syringe and mix well to disperse the insulin thoroughly. Failure to do this may result in unexpected hypoglycaemia.
- 4. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 5. Give by IV injection or infusion over 5-15 minutes.

#### **Continuous subcutaneous insulin infusion (CSII)**

- 1. Prepare following the manufacturer's guidelines.
- 2. The cannula should be replaced and repositioned every 3 days.<sup>4</sup>

| Technical information |                                                                                                                                                                                                                                                                                                                                                                                                          |  |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Incompatible with     | Insulin is adsorbed on to the surface of infusion containers; this can be<br>decreased by using small-volume containers, e.g. syringe pumps rather than<br>large infusion bags.<br>Drotrecogin alfa (activated), labetalol, micafungin, ranitidine.                                                                                                                                                      |  |
| Compatible with       | Flush: NaCl 0.9%<br>Solutions: NaCl 0.9%, Gluc 5% (including added KCl)<br>Y-site: Co-administration of drugs is not recommended because of the risk of<br>inadvertently affecting insulin infusion rate. In DKA insulin may be infused in the<br>same line as infusion fluids provided a Y-connector with a one-way anti-siphon<br>valve is used and a large-bore cannula has been placed. <sup>2</sup> |  |
| рН                    | 7-7.8 (but dependent on product)                                                                                                                                                                                                                                                                                                                                                                         |  |
| Sodium content        | Negligible                                                                                                                                                                                                                                                                                                                                                                                               |  |
| Excipients            | Most insulins contain metacresol (may cause hypersensitivity reactions) - see individual product literature.                                                                                                                                                                                                                                                                                             |  |
| Storage               | Store at 2-8°C in original packaging. Do not freeze.<br>In use: May be used and stored at room temperature for up to 28 days (some<br>products are stable for 42 days - see individual product literature).<br>Pens in use should not be stored in the fridge (pens may jam) or with needles<br>attached. Replace the pen cap between injections to protect from light.                                  |  |

Use prepared infusions immediately.

# Monitoring

| Measure                                               | Frequency                                                                                                    | Rationale                                                                                                                                                                     |
|-------------------------------------------------------|--------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Capillary blood<br>glucose (during IV<br>infusion)    | Every 60 minutes                                                                                             | <ul> <li>For signs of clinical improvement (in DKA and HHS).</li> <li>To maintain blood glucose within normal range and avoid hypoglycaemia if the patient is NBM.</li> </ul> |
| Capillary blood<br>glucose (during SC<br>maintenance) | Pre-meals, at bedtime and if<br>hypoglycaemia is suspected<br>(or as recommended by the<br>patient's clinic) | <ul> <li>To monitor adequacy of insulin regimen and<br/>to facilitate dose adjustment.</li> <li>To ensure that hypoglycaemia is treated<br/>appropriately.</li> </ul>         |
| Blood (or urine)<br>ketones                           | Every 60 minutes in DKA                                                                                      | • For signs of clinical improvement.                                                                                                                                          |
| U&Es                                                  | Every 2 hours in DKA and<br>HHS, daily during IV infusion<br>while NBM                                       | <ul> <li>To assess whether K-containing fluids are required and to avoid ↓K.</li> <li>To avoid ↓Na and assess state of hydration.</li> </ul>                                  |
| Blood<br>bicarbonate, pH                              | Every 2 hours in DKA - venous samples are adequate <sup>2</sup>                                              | • For signs of clinical improvement.                                                                                                                                          |
| HbA <sub>1c</sub>                                     | Every 3-6 months                                                                                             | • To assess adequacy of control of diabetes mellitus.                                                                                                                         |
| Monitoring of<br>diabetic<br>complications            | Annually (or more frequently if appropriate)                                                                 | <ul> <li>To ensure that complications are treated or<br/>dealt with, and that the patient is counselled<br/>appropriately.</li> </ul>                                         |

# Additional information

| Common and<br>serious<br>undesirable<br>effects | <ul> <li>Injection/infusion-related:</li> <li>Too rapid administration: Hypoglycaemia.</li> <li>Local: Pain, itching, swelling or inflammation at SC injection sites that usually reduces with continued use. Injection sites should be rotated. Lipoatrophy or lipohypertrophy from overuse of sites (less common with highly purified insulins).</li> <li>Other: Hypoglycaemia, ↓K.</li> </ul>                                                          |
|-------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Pharmacokinetics                                | Onset of action is instantaneous if given IV irrespective of the formulation used, i.e. an inadvertent IV dose of a long-acting insulin will have immediate effect. Elimination half-life is a few minutes after IV administration. Duration of action is dependent on insulin formulation if give by SC injection. Action may be prolonged in severe renal impairment. In $\uparrow K$ , effects are seen in 15 minutes and last 4-6 hours. <sup>3</sup> |

#### 456 | Insulins

| Additional in                 | Additional information (continued)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |  |  |
|-------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|--|
| Significant<br>interactions   | <ul> <li>No significant interactions; however, any medication affecting blood glucose control may necessitate an adjustment in insulin dosage.</li> <li>The following may ↓blood glucose levels: ethanol, quinine (parenteral).</li> <li>The following may ↑blood glucose levels: antipsychotics-atypical, beta-agonists (parenteral), combined oral contraceptives, glucocorticoids, protease inhibitors, diuretics-thiazide.</li> </ul>                                                                                                                                        |  |  |
| Action in case of<br>overdose | Symptoms to watch for: Hypoglycaemia: excessive sweating, pallor, palpitations, trembling, feeling cold, impaired vision, irritability, tingling round the lips, inability to concentrate, confusion, personality change, inability to waken.<br>Antidote: Rapidly absorbed oral carbohydrate. If unconscious, glucagon by IM or SC injection or glucose by slow IV injection (see relevant monographs).                                                                                                                                                                         |  |  |
| Counselling                   | Correct administration of insulin, insulin storage, disposal of sharps, importance of<br>taking doses regularly as prescribed.<br>Training in use of blood glucose, blood ketone or urine glucose monitoring as<br>appropriate.<br>Patients maintained on insulin should always carry glucose (and glucagon if<br>necessary) and should be able to recognise the symptoms of hypoglycaemia.<br>Relatives or carers should be trained to recognise hypoglycaemia and how to treat it<br>appropriately.<br>Contact number for advice for newly diagnosed insulin-treated patients. |  |  |

 
 Risk rating: RED
 Score = 6 High-risk product: Risk-reduction strategies are required to minimise these risks.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

| >20                        | 6 (and seek medical input)    |

<sup>a</sup>For patients with Type 1 diabetes mellitus, the insulin infusion rate should never be decreased to zero unless Lantus or Levemir insulins are also being given.

# Intralipid

#### 10% emulsion in 100-mL and 500-mL infusion containers 20% emulsion in 100-mL, 250-mL and 500-mL infusion containers 30% in 333-mL infusion container

- Intralipid contains fractionated soya oil in the form of a fat emulsion. It is a rich source of linoleic and linolenic acids, which are essential fatty acids.
- Fat emulsions such as Intralipid are used in combination with other nutrients in parenteral nutrition regimens to provide a high energy intake in a relatively small volume.
- Intralipid may also be used (unlicensed) for 'lipid rescue' to treat severe local anaesthetic toxicity
  resulting from inadvertent systemic administration of epidural and other preparations.

#### **Pre-treatment checks**

- Do not give to patients with severe egg allergy.
- Use with caution in patients known to be allergic to soya protein, and only after hypersensitivity tests.
- Caution in conditions of impaired lipid metabolism such as renal insufficiency, uncontrolled diabetes mellitus, pancreatitis, certain forms of liver insufficiency, hypothyroidism (if hypertriglyceridaemic), metabolic disorders and sepsis.

Biochemical and other tests (not all are necessary in an emergency situation)

|---------------|---------------------------------------|
| LFTs          | TFTs                                  |
| Lipid profile |                                       |

#### Dose

**Total parenteral nutrition:** the dose is tailored to the energy requirements and the clinical status of the patient as well as the patient's ability to utilise fat. Energy requirements of individuals must be met if amino acids are to be utilised for tissue maintenance rather than as an energy source. Parenteral feeding should be introduced slowly initially, particularly in those patients at risk of refeeding syndrome, e.g. the chronically malnourished.

**Prevention and correction of essential fatty acid deficiency (EFAD):** when given to prevent or correct essential fatty acid deficiency, 4–8% of non-protein calories should be supplied as Intralipid to provide sufficient amounts of linoleic and linolenic acids.

**Treatment of local anaesthetic induced cardiac arrest that is unresponsive to standard therapy:** data is still extremely limited; there are no standard methods for lipid emulsion therapy. The following regimen has been suggested.<sup>1,2</sup> It should be used only after standard resuscitation methods fail to re-establish sufficient circulatory stability.

The following doses are of Intralipid 20%:

- 1. 1.5 mL/kg over 1 minute.\*
- 2. Follow immediately with an IV infusion at a rate of 0.25 mL/kg/minute.\*
- 3. Continue chest compressions (lipid must circulate).
- 4. Repeat 1.5 mL/kg bolus every 3-5 minutes up to 3 mL/kg total dose until circulation is restored.
- Continue infusion until haemodynamic stability is restored. Increase the rate to 0.5 mL/kg/ minute if BP declines.\*
- 6. A maximum total dose of 8 mL/kg is recommended.

#### \*In practice, for a 70-kg adult:

- Withdraw 50 mL from a 500-mL Intralipid 20% container and give immediately (twice).
- Attach the Intralipid 20% container to a giving set give by IV infusion over the next 15 minutes.
- · Repeat the initial bolus up to twice more, if spontaneous circulation has not returned.

#### Intravenous infusion

- Intralipid may be given as a separate infusion or (more commonly now) as an 'all-in-one' admixture.
- Parenteral nutrition admixtures must be prepared in a pharmacy aseptic unit and must be compounded for physical stability.
- When separate infusion is preferred, the fat emulsion may be infused into the same central or peripheral vein as carbohydrate/amino acid solutions via a Y-connector close to the infusion site.
- It has been recommended that administration sets used for lipid emulsions be changed within 24 hours of initiating infusion because of the potential for bacterial and fungal contamination.
- On the first day of infusion it is advisable to give a maximum of 5 mL/kg Intralipid 20% or 10 mL/kg Intralipid 10%. Subsequently the dose is usually increased and, when a larger intake is indicated, the dose may be increased to a maximum of 3 g/kg/day.
- Intralipid 10% 500 mL should be given over a period not less than 3 hours.
- Intralipid 20% 500 mL should be given over a period of not less than 5 hours.
- Intralipid 30%: the rate for the first half-hour should be half the final administration rate. The infusion rate should not exceed 333 mL in 5 hours.

# Iron dextran (CosmoFer)

#### Iron (as iron dextran) 50 mg/mL solution in 2-mL, 5-mL and 10-mL ampoules

- Iron is an essential element, being necessary for haemoglobin formation and the storage of oxygen in living cells. Iron deficiency results in defective erythropoiesis and anaemia.
- Iron dextran complex is used to treat iron deficiency when oral iron preparations cannot be used (for example owing to intolerance), when oral preparations have had a demonstrated lack of effect, or when rapid replenishment of iron stores is necessary.
- Each millilitre of CosmoFer injection contains 50 mg of ferric iron as iron(III)-hydroxide dextran complex.

#### **Pre-treatment checks**

- Not to be given in: history of allergic disorders including asthma and eczema; infection; active rheumatoid arthritis; severe hepatic impairment; acute renal failure.
- Not be used in the first trimester of pregnancy.
- Do not use in non-iron-deficiency anaemias, e.g. haemolytic anaemias, iron overload or disturbances in utilisation of iron.
- Owing to the potential risk of anaphylactoid reactions, resuscitation equipment and staff trained to
  evaluate and treat anaphylaxis should be available whenever a dose of iron dextran is administered.

#### Biochemical and other tests

Bodyweight FBC (including Hb) LFTs Renal function: U, Cr, CrCl (or eGFR)

#### Dose

The total dose required to treat iron-deficiency anaemia and replenish iron stores is dependent on the initial Hb level and bodyweight (see Dose calculation below).

**Standard dose:** give 100–200 mg (2–4 mL) by IV injection or infusion 2–3 times weekly until the calculated dose has been given.

Alternatively, give doses of 100–200 mg (2–4 mL) by IM injection. For moderately active patients, give injections daily into alternate buttocks; in relatively inactive or frail patients, give injections once or twice weekly. Continue administration until the calculated dose has been given.

**Total dose infusion for rapid replenishment of iron stores (hospital use only):** up to 20 mg/kg/day by IV infusion may be given. If the calculated total dose required exceeds 20 mg/kg/ day, the administration must be split over two days (see Table I6 below).

**Dose calculation for iron-deficiency anaemia:** the desired dose may be calculated from the following equations (dependent on the unit of measure for Hb), which apply to a bodyweight >35 kg; or use Table I6 below. The dose should be rounded to the nearest easily measurable volume.

#### For Hb reported in g/dL:

Total dose required (mg iron) = [bodyweight (kg) × (target Hb – actual Hb) × 2.4] + 500

#### For Hb reported in mmol/L:

Total dose required (mg iron) = [bodyweight (kg) × (target Hb – actual Hb) × 3.84] + 500

**Iron replacement for blood loss:** the aim is to replace the iron content of the estimated blood loss. Giving 200 mg (4 mL) by IV injection or infusion results in an increase in Hb roughly equivalent to that supplied by one unit of blood.

#### Intermittent intravenous infusion (preferred route)

#### Preparation and administration

- 1. Withdraw the required dose and add to a suitable volume of NaCl 0.9% (100 mL for standard dose; 500 mL for total dose infusion).
- 2. The solution should be dark brown. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Initial test dose (prior to first dose only): Give the first 25 mg by IV infusion over 15 minutes; stop the infusion and observe the patient carefully for signs of allergic reaction for at least 60 minutes; if no adverse effects are seen give the remainder of the infusion.
- For the standard dose give the dose by IV infusion over 30 minutes; for a total dose infusion give the dose by IV infusion over 4–6 hours.
- 5. Observe the patient carefully for a minimum of 1 hour after total dose infusion.

#### Intramuscular injection

#### Preparation and administration

- Initial test dose (prior to first dose only): Withdraw 25 mg (0.5 mL) and give by IM injection following the procedure outlined in points 2–6 below. Observe the patient carefully for signs of allergic reaction for at least 60 minutes; if no adverse effects are seen give the remainder of the dose.
- 2. Withdraw the required dose (or the remainder of the dose if a test dose has been given). Up to 2 mL may be given at each administration (total dose required is determined by dosage calculation).

 Table 16
 Total dose of CosmoFer for iron-deficiency anaemia in mL (based on bodyweight and initial Hb)

- 3. Attach a  $20-21G \times 50$ -mm needle for average-sized adults (use  $23G \times 32$ -mm needle for smaller adults;  $20-21G \times 80-100$ -mm needle for obese adults).
- 4. The patient should be positioned in the lateral position with the injection site uppermost, or standing bearing their weight on the leg opposite the injection site.
- 5. Using the Z-track technique, give the dose smoothly and slowly by deep IM injection into the muscle mass of the upper outer quadrant of the buttock. It must never be given into the arm or other exposed areas as there is a risk of SC staining.
- 6. Leave the needle *in situ* for a few seconds before withdrawal to allow the muscle mass to accommodate the injection volume. To minimise leakage up the injection track, the patient should be advised not to rub the injection site. Rotate injection sites for subsequent injections.

### Intravenous injection (or injection into the venous limb of a dialyser)

#### Preparation and administration

- 1. Withdraw the required dose (2–4 mL) and dilute to a final volume of 10–20 mL with NaCl 0.9% to produce a solution containing 10 mg/mL.
- The solution should be dark brown. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Initial test dose (prior to first dose only): Give 2.5 mL (25 mg) of the diluted injection by IV injection over 1–2 minutes. Observe the patient carefully for signs of allergic reaction for at least 15 minutes; if no adverse effects are seen, give the remainder of the injection.
- 4. Give the diluted injection by IV injection at a maximum rate of 1 mL/minute.

# Iron sucrose (Venofer)

#### 20 mg/mL solution in 5-mL ampoules

- Iron is an essential element, being necessary for haemoglobin formation and the storage of oxygen in living cells. Iron deficiency results in defective erythropoiesis and anaemia.
- Iron sucrose complex is used to treat iron deficiency when oral iron preparations cannot be used (for example owing to intolerance), when oral preparations have had a demonstrated lack of effect, or when rapid replenishment of iron stores is necessary.
- Some patients who have had prior hypersensitivity reactions to iron dextran may tolerate iron sucrose better. Should treatment with iron sucrose be contemplated in these patients, a full treatment plan (including monitoring and treatment of hypersensitivity reactions) should be prepared.
- Each millilitre of Venofer injection contains 20 mg of ferric iron as iron (III)-hydroxide sucrose complex.

#### **Pre-treatment checks**

- Not to be given in: history of allergic disorders including asthma and eczema.
- Not be used in the first trimester of pregnancy.
- Do not use in non-iron-deficiency anaemias, e.g. haemolytic anaemias, iron overload or disturbances in utilisation of iron.
- Caution in hepatic impairment; in case of acute or chronic infection (the manufacturer recommends that the administration is stopped in patients with ongoing bacteraemia).
- Owing to the potential risk of anaphylactoid reactions, resuscitation equipment and staff trained to
  evaluate and treat anaphylaxis should be available whenever a dose of iron sucrose is administered.

#### Biochemical and other tests

Bodyweight FBC (including Hb) LFTs

#### Dose

The total dose required to treat iron-deficiency anaemia and replenish iron stores is dependent on the initial Hb level and bodyweight (see Dose calculation below).

**Standard dose**: 100–200 mg by IV injection or infusion up to 2–3 times a week until the calculated dose has been given.

**Dose calculation for iron-deficiency anaemia:** the desired dose may be calculated from the following equations (dependent on the unit of measure for Hb) which apply to a bodyweight >35 kg; or use Table I7 below. The dose should be rounded to the nearest easily measurable volume.

#### For Hb reported in g/dL:

 $\label{eq:total_total_total_total} Total \ dose \ required \ (mg \ iron) = [bodyweight \ (kg) \times (target \ Hb - actual \ Hb) \times 2.4] + 500 \\ \ For \ Hb \ reported \ in \ mmol/L:$ 

 $Total \ dose \ required \ (mg \ iron) = [bodyweight \ (kg) \times (target \ Hb - actual \ Hb) \times 3.84] + 500$ 

#### Intermittent intravenous infusion

#### Preparation and administration

- 1. Withdraw the required dose and add to a suitable volume of NaCl 0.9% to produce a solution containing no less than 1 mg/mL (i.e. add 100 mg to 50–100 mL; add 200 mg to 100–200 mL).
- 2. The solution should be brown and clear. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Initial test dose (prior to first dose only): give the first 25 mg by IV infusion over 15 minutes; stop the infusion and observe the patient carefully for signs of allergic reaction; if no adverse effects are seen, give the remainder of the infusion.
- Give by IV infusion via a volumetric infusion device as follows: give 100 mg over at least 15 minutes; give 200 mg over at least 30 minutes.

#### Intravenous injection (or injection into the venous limb of a dialyser)

#### Preparation and administration

- 1. Withdraw the required dose.
- The solution should be brown and free of sediment. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Initial test dose (prior to first dose only): give 1 mL of undiluted injection by IV injection over 1–2 minutes. Observe the patient carefully for signs of allergic reaction for at least 15 minutes; if no adverse effects are seen, give the remainder of the injection.
- Give undiluted injection by IV injection at a maximum rate of 1 mL/minute (i.e. 5 minutes per ampoule).

| <ul> <li>Iron sucrose may ↑levels or effect of the following drugs (or ↑side-effects): dimercaprol (avoid combination - may result in serious toxicity).</li> <li>Iron sucrose may ↓levels or effect of oral iron salts (↓absorption - do not start within 5 days of parenteral treatment).</li> </ul>                                                                                                                                                                         |  |  |
| <i>Symptoms to watch for:</i> Acute iron overload which may appear as haemosiderosis.<br><i>Antidote:</i> Iron chelation therapy can be used.                                                                                                                                                                                                                                                                                                                                  |  |  |
| Advise the patient to report any hypersensitivity reactions.                                                                                                                                                                                                                                                                                                                                                                                                                   |  |  |
|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |  |  |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# **Bibliography**

SPC Venofer (accessed 24 August 2009).

# Isoniazid

#### 25 mg/mL solution in 2-mL ampoules

- · Isoniazid is a hydrazide derivative that is bactericidal against actively dividing Mycobacterium tuberculosis.
- · It is used as part of multidrug regimens in the primary treatment of pulmonary and extrapulmonary tuberculosis and for tuberculosis prophylaxis in high-risk subjects.
- · Isoniazid is well absorbed from the GI tract following oral dosing, so parenteral routes should be used only when the oral route is unavailable.

#### 472 | Isoniazid

- Pyridoxine (10–50 mg daily) is commonly co-prescribed with isoniazid to those predisposed to peripheral neuropathy, e.g. malnourishment, chronic renal impairment, diabetes, HIV infection, and in alcohol dependence.
- Isoniazid injection is also licensed for intrapleural use (50–250 mg is instilled intrapleurally after aspiration of pus; the oral dose is correspondingly reduced on the same day) and for intrathecal use. It may also be used to treat infected ulcers and irrigate fistulae.

#### **Pre-treatment checks**

- Caution if there is a history of seizures or psychotic reactions (†risk).
- · Check drug interactions if the patient is on antiepileptic drugs.
- If the patient is a 'slow acetylator' (genetically determined metabolic pathway) they may be more susceptible to drug-induced peripheral neuropathy (in rare instances this may require a dose reduction to 200 mg daily).
- Caution also in alcohol dependence, malnutrition, diabetes mellitus, HIV infection (risk of peripheral neuropathy) and acute porphyria.

#### Biochemical and other tests

LFTs (use cautiously in chronic alcoholism and pre-existing hepatitis) Renal function: U, Cr, CrCl (or eGFR)

#### Dose

**Dose for 2-month initial and 4-month continuation phases:** 300 mg as a single daily dose. **Dose for intermittent supervised 6-month treatment:** 15 mg/kg (max. 900 mg) 3 times a week. **Dose in renal impairment:** in patients with CrCl <10 mL/minute the dose *may* need to be reduced to 200 mg daily (see Monitoring below).

#### Intramuscular injection

#### Preparation and administration

- 1. Withdraw the required dose.
- 2. Give by IM injection. Volumes > 4 mL should be distributed between two or more injection sites.

#### Intravenous injection

Preparation and administration

Isoniazid is incompatible with Gluc 5%.

- 1. Withdraw the required dose.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV injection over 3-5 minutes.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Isoniazid ampoules 50 mg/2 mL, Cambridge Laboratories (accessed 24 March 2009).

# Isosorbide dinitrate (ISDN)

#### 500 micrograms/mL (0.05%) solution in 50-mL vials

#### 1 mg/mL (0.1%) solution in 10-mL ampoules; 50-mL and 100-mL vials

- Isosorbide dinitrate is a vasodilator that relaxes smooth vascular muscle, reducing cardiac filling
  pressure and volume (pre-load) and lowering myocardial oxygen demand.
- It is used in the treatment of unresponsive left ventricular failure of various aetiologies and severe to unstable angina pectoris.
- It is also is used during percutaneous transluminal coronary angioplasty to facilitate prolongation of balloon inflation and to prevent or relieve coronary spasm.

#### **Pre-treatment checks**

- Contraindicated in severe anaemia, ↑intracranial pressure due to head trauma or cerebral haemorrhage, uncorrected hypovolaemia and hypotensive shock, arterial hypoxaemia and angina caused by hypertrophic obstructive cardiomyopathy, constrictive pericarditis, pericardial tamponade or toxic pulmonary oedema.
- Caution in severe renal/hepatic impairment, hypothyroidism, malnutrition, or hypothermia.

#### Biochemical and other tests (not all are necessary in an emergency situation)

Blood pressure Electrolytes: serum Na, K Heart rate LFTs Renal function: U, Cr, CrCl (or eGFR) TFTs

#### Dose

#### Unresponsive left ventricular failure of various aetiologies and severe angina pectoris:

initially 2 mg/hour titrated against individual clinical response (usual range is 2–12 mg/hour but up to 20 mg/hour may be required).

## Continuous intravenous infusion via syringe pump

Preparation and administration

Avoid use of PVC infusion containers, administration sets and in-line filters if possible. Rigid plastics, i.e. polyethylene or polypropylene administration sets and syringes, should be used if available.

- Withdraw 50 mL of the 500 micrograms/mL strength into a syringe suitable for use with a syringe pump. Alternatively, withdraw 25 mL of the 1 mg/mL strength and make up to 50 mL with NaCl 0.9%. Cap the syringe and mix well to give a solution containing 500 micrograms/mL.
- The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.
- 3. Give by IV infusion using a syringe pump. For most indications the starting infusion rate is 2 mg/hour (4 mL/hour). Adjust dose to clinical response as indicated above.

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Isoket 0.05%, Isoket 0.1% (accessed 28 April 2009).

# Itraconazole

#### 10 mg/mL solution in 25-mL vials (with 50 mL NaCl 0.9% infusion bag and in-line filter)

- Itraconazole is a triazole antifungal drug.
- It is used in the treatment of systemic aspergillosis, candidiasis and cryptococcosis including cryptococcal meningitis where other antifungal drugs are inappropriate or ineffective, and also in histoplasmosis.

#### **Pre-treatment checks**

- Check drug interactions for contraindications.
- The UK CSM has advised caution in patients at high risk of heart failure, i.e. patients receiving high doses and longer treatment courses, older patients and those with cardiac disease, and patients receiving treatment with negative inotropic drugs, e.g. calcium channel antagonists.
- Oral absorption is reduced in AIDS and neutropenia (†dose if necessary).

#### Biochemical tests

| Electrolytes: serum K | LFTs                                  |
|-----------------------|---------------------------------------|
| FBC                   | Renal function: U, Cr, CrCl (or eGFR) |

#### Dose

**Standard dose**: 200-mg by IV infusion twice daily for 2 days, then 200 mg daily by IV infusion for up to 12 days.

Dose in renal impairment: do not use if CrCl < 30 mL/minute.

Dose in hepatic impairment: use with caution only if benefit exceeds the risk of hepatic injury.

## Intermittent intravenous infusion

Vials (and prepared infusions) contain an overage. When the infusion is prepared as directed, a 200-mg dose is contained in 60 mL.

The infusion must be stopped after 200 mg (60 mL) has been given.

#### Preparation

- 1. Withdraw the entire vial contents and add to the 50-mL bag of NaCl 0.9% provided (no other bag should be used).
- Gently mix the contents of the infusion bag to give a solution containing 3.33 mg/mL (200 mg/ 60 mL).
- 3. The solution should be clear and colourless. Inspect visually for particulate matter or discoloration prior to administration and discard if present.

#### Administration

- 1. Attach a standard infusion line to the infusion bag and fill the drip chamber to half full by squeezing (pumping) it.
- Connect the infusion line to the two-way stop cock provided, which includes a 0.2 micron in-line filter, and prime the line. Exposure to normal room light during infusion is acceptable, but protect from direct sunlight.
- Give by IV infusion via a volumetric infusion device at a rate of 60 mL/hour. Administer 60 mL only of the solution over 60 minutes then stop the infusion (this provides the 200-mg dose).
- Flush the extension line with 15–20 mL NaCl 0.9% at the two-way stop cock (just before the inline filter), allowing the flush to run continuously for between 30 seconds and 15 minutes.

## 478 | Itraconazole

| Technical information          |                                                                                                                                                                                                                                                                                 |  |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|
| Incompatible with              | Itraconazole is incompatible with Gluc 5%, Gluc-NaCl, Hartmann's, Ringer's<br>(precipitation likely).<br>Do not mix with other drugs during infusion.                                                                                                                           |  |
| Compatible with                | Flush: NaCl 0.9%<br>Solutions: NaCl 0.9%<br>Y-site: No information but likely to be unstable.                                                                                                                                                                                   |  |
| рН                             | 4.5                                                                                                                                                                                                                                                                             |  |
| Sodium content                 | 7.7 mmol (from 50-mL infusion bag)                                                                                                                                                                                                                                              |  |
| Excipients                     | Contains propylene glycol (adverse effects seen in ↓renal function, may interact with disulfiram and metronidazole).                                                                                                                                                            |  |
| Storage                        | Store below 25°C in original packaging.                                                                                                                                                                                                                                         |  |
| Stability after<br>preparation | Protect from direct sunlight during infusion - exposure to normal room light<br>is acceptable.<br>From a microbiological point of view, should be used immediately; however,<br>prepared infusions may be stored at 2-8°C and infused (at room temperature)<br>within 24 hours. |  |

# Monitoring

| Action in case of<br>overdose             | There is no specific antidote and it is not removed by haemodialysis. General supportive methods should be employed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |  |
| Counselling                               | Patients should be told how to recognise signs of liver disorder and advised to seek prompt medical attention if symptoms such as anorexia, nausea, vomiting, fatigue, abdominal pain or dark urine develop.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |  |
|                                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |

This assessment is based on the full range of preparation and administration options described in the monograph. These may not all be applicable in some clinical situations.

# Bibliography

SPC Sporanox IV (accessed 24 March 2009).

# Ketamine

# 10 mg/mL solution in 20-mL vials; 50 mg/mL solution in 10-mL vials; 100 mg/mL solution in 10-mL vials

- · Ketamine hydrochloride is a general anaesthetic agent.
- · It is used for the induction and maintenance of anaesthesia and as a supplementary anaesthetic.
- It may also be used (unlicensed) for its analgesic action in neuropathic and other pain unresponsive to conventional analgesics. Routes of administration and doses used vary widely.
- Ketamine has abuse potential; if it is used regularly for a few weeks, dependence and tolerance may develop.
- Doses are expressed in terms of the base: Ketamine 1 mg ≅ 15 mg ketamine hydrochloride.

#### **Pre-treatment checks**

- Avoid in patients where *†BP* may be dangerous, patients with eclampsia or pre-eclampsia, severe coronary or myocardial disease, cerebrovascular accident or cerebral trauma.
- If it is being used for elective surgery, ensure that the patient has been nil by mouth for 6 hours prior to anaesthesia.

#### Biochemical and other tests

Blood pressure Bodyweight

#### Dose

**Short procedures by IM injection:** initially 6.5–13 mg/kg. A dose of 4 mg/kg is used for diagnostic manoeuvres and procedures not involving intense pain. A dose of 10 mg/kg will usually produce 12–25 minutes of surgical anaesthesia.

**Short procedures by IV injection:** initially 1–4.5 mg/kg. A dose of 2 mg/kg will usually produce 5–10 minutes of surgical anaesthesia.

For induction and longer procedures by IV infusion: at induction use a total dose of 0.5–2 mg/kg; for maintenance use 10–45 micrograms/kg/minute adjusted according to patient response.

#### Intramuscular injection

Preparation and administration

Check that you have selected the correct strength of vial.

- 1. Withdraw the required dose.
- 2. Give by IM injection.

### Intravenous injection

Preparation and administration

Check that you have selected the correct strength of vial.

- 1. Withdraw the required dose.
- 2. If using the 100 mg/mL strength dilute with an equal volume of WFI, NaCl 0.9% or Gluc 5%.
